

**EN39SL800****8 Megabit (512K x 16-bit) Flash Memory With 4Kbytes Uniform Sector, CMOS 1.8 Volt-only****FEATURES**

- Single power supply operation
  - Full voltage range: 1.65-1.95 volt for read and write operations.
  - Ideal for battery-powered applications.
- High performance
  - Access times as fast as 70 ns
- Low power consumption (typical values at 5 MHz)
  - 5 mA typical active read current
  - 15 mA typical program/erase current
  - 0.2  $\mu$ A typical standby current
- Uniform Sector Architecture:
  - 256 sectors of 2-Kword
  - 16 blocks of 32-Kword
  - Any sector or block can be erased individually
- Block protection:
  - Hardware locking of blocks to prevent program or erase operations within individual blocks
- Chip Unprotect Mode
- High performance program/erase speed
  - Word program time: 8 $\mu$ s typical
  - Sector erase time: 90ms typical
  - Block erase time: 180ms typical
  - Chip erase time: 2s typical
- JEDEC Standard Embedded Erase and Program Algorithms
- JEDEC standard DATA# polling and toggle bits feature
- Single Sector, Block and Chip Erase
- Erase Suspend / Resume modes:
  - Read or program another Sector/Block during Erase Suspend Mode
- Support JEDEC Common Flash Interface (CFI).
- Low Vcc write inhibit  $\leq$  1.2V
- Minimum 100K endurance cycle
- Package Options
  - 48-ball 6mm x 8mm TFBGA
  - 48-ball 4mm x 6mm WFBGA
- Industrial temperature Range

**GENERAL DESCRIPTION**

The EN39SL800 is an 8-Megabit, electrically erasable, read/write non-volatile flash memory, organized as 524,288 words. Any word can be programmed typically in 8 $\mu$ s. The EN39SL800 features 1.8V voltage read and write operation, with access time as fast as 70ns to eliminate the need for WAIT statements in high-performance microprocessor systems.

The EN39SL800 has separate Output Enable (OE#), Chip Enable (CE#), and Write Enable (WE#) controls, which eliminate bus contention issues. This device is designed to allow either single Sector/Block or full chip erase operation, where each block can be individually protected against program/erase operations or chip unprotected to erase or program. The device can sustain a minimum of 100K program/erase cycles on each sector or block.

PRODUCT SELECTOR GUIDE

Product Number		EN39SL800
Speed Option	Full Voltage Range: Vcc=1.65 – 1.95 V	-70
Max Access Time, ns (t <sub>acc</sub> )		70
Max CE# Access, ns (t <sub>ce</sub> )		70
Max OE# Access, ns (t <sub>oe</sub> )		30

BLOCK DIAGRAM

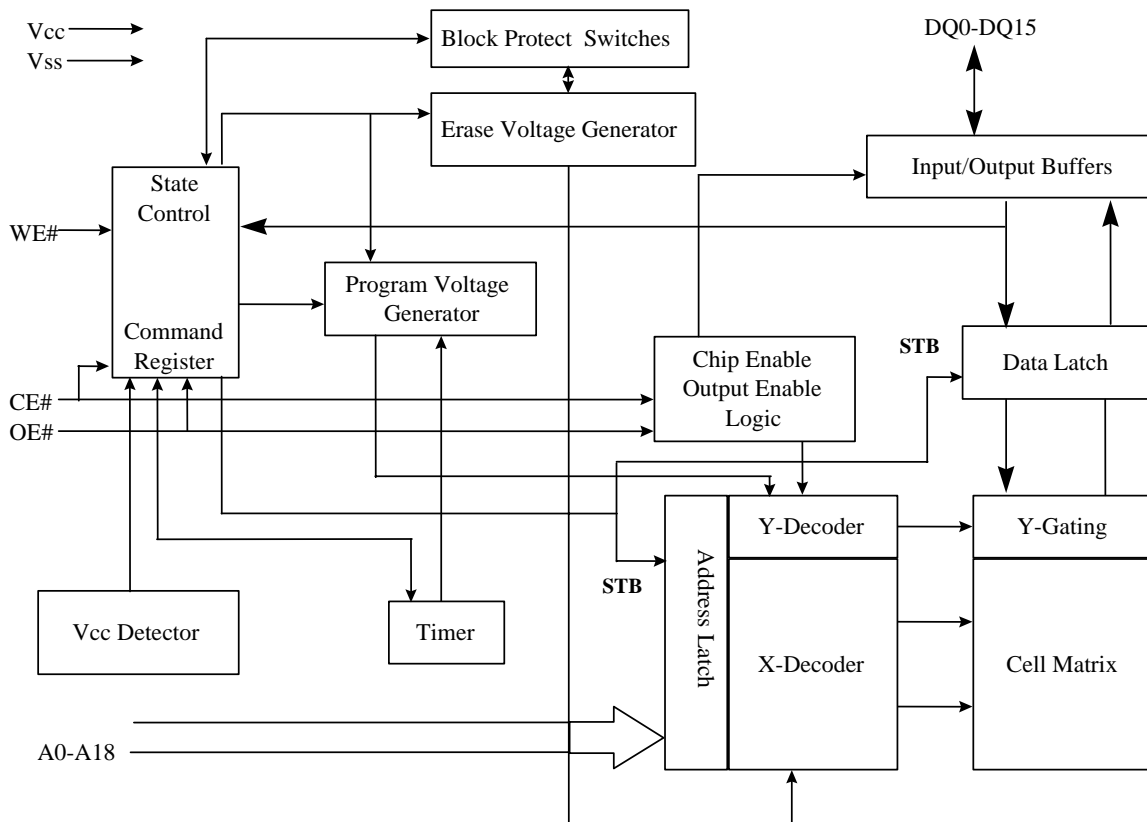

Table 3. OPERATING MODES

**8M FLASH USER MODE TABLE**

Operation	CE#	OE#	WE#	A0-A18	DQ0-DQ15
Read	L	L	H	A <sub>IN</sub>	D <sub>OUT</sub>
Write	L	H	L	A <sub>IN</sub>	D <sub>IN</sub>
CMOS Standby	V <sub>CC</sub> ± 0.2V	X	X	X	High-Z
Output Disable	L	H	H	X	High-Z
Block Protect	L	H	L	Block Address, A6 = L, A1 = H, A0 = L	D <sub>IN</sub>
Chip Unprotect	L	H	L	Block Address, A6 = L, A1 = H, A0 = L	D <sub>IN</sub>

## Notes:

L=logic low= V<sub>IL</sub>, H=Logic High= V<sub>IH</sub>, V<sub>ID</sub> = 10.0 ± 1.0V, X=Don't Care (either L or H, but not floating!),  
D<sub>IN</sub>=Data In, D<sub>OUT</sub>=Data Out, A<sub>IN</sub>=Address In

Table 4. DEVICE IDENTIFICATION (Autoselect Codes)

**8M FLASH MANUFACTURER/DEVICE ID TABLE**

Description	CE#	OE#	WE#	A18 to A15	A14 to A10	A9 <sup>2</sup>	A8	A7	A6	A5 to A2	A1	A0	DQ8 to DQ15	DQ7 to DQ0
Manufacturer ID: Eon	L	L	H	X	X	V <sub>ID</sub>	H <sup>1</sup>	X	L	X	L	L	X	1Ch
							L							7Fh
Device ID	L	L	H	X	X	V <sub>ID</sub>	X	X	L	X	L	H	27h	3Fh
Block Protection Verification	L	L	H	BA	X	V <sub>ID</sub>	X	X	L	X	H	L	X	01h (Protected)
													X	00h (Unprotected)

## Note:

- A8=H is recommended for Manufacturing ID check. If a manufacturing ID is read with A8=L, the chip will output a configuration code 7Fh.
- A9 = VID is for HV A9 Autoselect mode only. A9 must be ≤ V<sub>CC</sub> (CMOS logic level) for Command Autoselect Mode.

## **USER MODE DEFINITIONS**

### **Standby Mode**

The EN39SL800 has a CMOS-compatible standby mode, which reduces the current to  $< 0.2\mu\text{A}$  (typical). It is placed in CMOS-compatible standby when the CE# pin is at  $V_{\text{CC}} \pm 0.2$ . When in standby modes, the outputs are in a high-impedance state independent of the OE# input.

### **Read Mode**

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data. The device is also ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the device enters the Erase Suspend mode. The system can read array data using the standard read timings, except that if it reads at an address within erase-suspended sectors/blocks, the device outputs status data. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception. See “Erase Suspend/Erase Resume Commands” for more additional information.

The system must issue the reset command to re-enable the device for reading array data if DQ5 goes high, or while in the autoselect mode. See the “Reset Command” additional details.

### **Output Disable Mode**

When the OE# pin is at a logic high level ( $V_{\text{IH}}$ ), the output from the EN39SL800 is disabled. The output pins are placed in a high impedance state.

### **Auto Select Identification Mode**

The autoselect mode provides manufacturer and device identification, and block protection verification, through identifier codes output on DQ15–DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires  $V_{\text{ID}}$  (9.0 V to 11.0 V) on address pin A9. Address pins A8, A6, A1, and A0 must be as shown in Autoselect Codes table. In addition, when verifying block protection, the block address must appear on the appropriate highest order address bits. Refer to the corresponding block Address Tables. The Command Definitions table shows the remaining address bits that are don't-care. When all necessary bits have been set as required, the programming equipment may then read the corresponding identifier code on DQ15–DQ0.

To access the autoselect codes in-system; the host system can issue the autoselect command via the command register, as shown in the Command Definitions table. This method does not require  $V_{\text{ID}}$ . See “Command Definitions” for details on using the autoselect mode.

### **Write Mode**

Write operations, including programming data and erasing sectors/blocks of memory, require the host system to write a command or command sequence to the device. Write cycles are initiated by placing the word address on the device's address inputs while the data to be written is input on DQ [15:0] in Word Mode. The host system must drive the CE# and WE# pins Low and the OE# pin High for a valid write operation to take place. All addresses are latched on the falling edge of WE# and CE#, whichever happens later. All data is latched on the rising edge of WE# or CE#, whichever happens first. The system is not required to provide further controls or timings. The device automatically provides internally generated program / erase pulses and verifies the programmed /erased cells' margin. The host system can detect

completion of a program or erase operation by reading the DQ[7] (Data# Polling) and DQ[6] (Toggle) status bits.

The 'Command Definitions' section of this document provides details on the specific device commands implemented in the EN39SL800.

## Block Protection and Chip Unprotection

The EN39SL800 includes the hardware block protection feature, which disables both program and erase operations in any block. The block protect feature is enabled using programming equipment at the user's site. Block is unprotected when the devices are shipped.

### Block Protection

To activate the block protection mode, the programming equipment must force  $V_{ID}$  on address pin A9 and control pin OE#, ( $V_{ID}=10V \pm 1.0V$ ),  $CE\# = WE\# = V_{IL}$ . The block addresses (A18-A15) should be set to the block to be protected while  $(A6, A1, A0) = (V_{IL}, V_{IH}, V_{IL})$ . Programming of the protection circuitry begins on the falling edge and is terminated with the rising edge of the WE# pulse. Addresses must be held constant during the WE# pulse. Please see Flowchart 7a for Block Protection Algorithms and Figure 11 for the waveform of timings.

Verification of the protection circuitry requires the programming equipment to apply  $V_{ID}$  on address pin A9 while OE# is set at  $V_{IL}$ , WE# is at  $V_{IH}$  and  $(A6, A1, A0) = (V_{IL}, V_{IH}, V_{IL})$ . To check for block protection, scanning of A18 – A15 while  $(A6, A1, A0) = (V_{IL}, V_{IH}, V_{IL})$  and activating CE# will produce 01H at the device's outputs (DQ0 – DQ7). During this mode, the lower addresses (except for A0, A1, and A6) are don't care (can be  $V_{IL}$  or  $V_{IH}$  but not floating).

The unspecified addresses are don't care which means they can be  $V_{IL}$ , or  $V_{IH}$ , but should not be floating. We also recommend that the data pins also be at  $V_{IL}$  or  $V_{IH}$  during the time that WE# is at  $V_{IL}$ .

### Chip Unprotection

Previously protected blocks can be unprotected using the chip unprotection algorithm as seen in Flowchart 7b and Figure 12 for the waveform of timings. All blocks must be placed in the protection mode using protection algorithm mentioned above before unprotection can be executed.

To activate the chip unprotection mode, the programming equipment must force  $V_{ID}$  on address pin A9 and control pin OE#, ( $V_{ID}=10V \pm 1.0V$ ),  $CE\# = WE\# = V_{IL}$ . And set addresses  $(A6, A1, A0) = (V_{IH}, V_{IH}, V_{IL})$ . The unprotection circuitry is then invoked by keeping WE# at  $V_{IL}$  for a length of  $t_{WPP2}$ .

To determine if unprotection is complete, each block must be verified. The chip unprotect verify mode is entered by setting  $OE\#=V_{IL}$ ,  $WE\#=V_{IH}$ , and raising A9 to  $V_{ID}$ . The unprotection status can then be read from DQ0-DQ7 by setting block address bits A18-A15 to the desired block address, and  $A6=1$ ,  $A1=1$ ,  $A0=0$ , and CE# to  $V_{IL}$ . A 00h on DQ0-DQ7 indicates that unprotection of that particular block is complete; otherwise repeat the process by re-entering the unprotection mode and re-invoking the unprotection circuitry for a period of  $t_{WPP2}$ . Repeat the process also if the unprotection status of any other blocks does not indicate 00h on DQ0-DQ7. When DQ0-DQ7 reads 00h for all blocks, chip unprotection is complete.

### Automatic Sleep Mode

The automatic sleep mode minimizes Flash device energy consumption. The device automatically enables this mode when addresses remain stable for  $t_{acc} + 30ns$ . The automatic sleep mode is independent of the CE#, WE# and OE# control signals. Standard address access timings provide new data when addresses are changed. While in sleep mode, output is latched and always available to the system.  $I_{cc4}$  in the DC Characteristics table represents the automatic sleep mode current specification.

## COMMON FLASH INTERFACE (CFI)

The Common Flash Interface (CFI) specification outlines device and host systems software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h in word mode, any time the device is ready to read array data.

The system can read CFI information at the addresses given in Tables 5-7. In word mode, the upper address bits (A7–MSB) must be all zeros. To terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode and the system can read CFI data at the addresses given in Tables 5–8. The system must write the reset command to return the device to the autoselect mode.

**Table 5. CFI Query Identification String <sup>(1)</sup>**

Adresses (Word Mode)	Data	Description
10h 11h 12h	0051h 0052h 0059h	Query Unique ASCII string "QRY"
13h 14h	0002h 0000h	Primary OEM Command Set
15h 16h	0040h 0000h	Address for Primary Extended Table
17h 18h	0000h 0000h	Alternate OEM Command set (00h = none exists)
19h 1Ah	0000h 0000h	Address for Alternate OEM Extended Table (00h = none exists)

1. Refer to CFI publication 100 for more details.

Table 6. System Interface String

Addresses (Word Mode)	Data	Description
1Bh	0016h	Vcc Min (write /erase) DQ7-DQ4: volts, DQ3 –DQ0: 100 millivolts
1Ch	0020h	Vcc Max (write /erase) DQ7-DQ4: volts, DQ3 –DQ0: 100 millivolts
1Dh	0000h	Vpp Min. voltage (00h = no Vpp pin present)
1Eh	0000h	Vpp Max. voltage (00h = no Vpp pin present)
1Fh	0004h	Typical timeout per single word program $2^N$ $\mu$ s
20h	0000h	Typical timeout for Min, size buffer write $2^N$ $\mu$ s (00h = not supported)
21h	000Ah	Typical timeout per individual sector/block erase $2^N$ ms
22h	0000h	Typical timeout for full chip erase $2^N$ ms (00h = not supported)
23h	0005h	Max. timeout for word write $2^N$ times typical
24h	0000h	Max. timeout for buffer write $2^N$ times typical
25h	0004h	Max. timeout per individual sector/block erase $2^N$ times typical
26h	0000h	Max timeout for full chip erase $2^N$ times typical (00h = not supported)

Table 7. Device Geometry Definition

Addresses (Word mode)	Data	Description
27h	0014h	Device Size = $2^N$ byte (14h = 20; $2^{20}$ = 1MByte)
2Ah	0000h	Max. number of byte in multi-byte write = $2^N$ (00h = not supported)
2Bh	0000h	
2Ch	0002h	Number of Erase Sector/Block Regions within device
2Dh	00FFh	Erase Sector Region 1 Information (y+1 = Number of sectors; z x 256B = sector size) y = 255 + 1 = 256 sectors (00FFh = 255) z = 16 x 256 Bytes = 4 KByte/sector (0010h = 16)
2Eh	0000h	
2Fh	0010h	
30h	0000h	
31h	000Fh	Erase Block Region 2 Information (y+1 = Number of blocks; z x 256B = block size) y = 15 + 1 = 16 blocks (000Fh = 15) z = 256 x 256 Bytes = 64 KByte/block (0100h = 256)
32h	0000h	
33h	0000h	
34h	0001h	

## Hardware Data Protection

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes as seen in the Command Definitions table. Additionally, the following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by false system level signals during Vcc power up and power down transitions, or from system noise.

### Low V<sub>CC</sub> Write Inhibit

When V<sub>CC</sub> is less than V<sub>LKO</sub>, the device does not accept any write cycles. This protects data during V<sub>CC</sub> power up and power down. The command register and all internal program/erase circuits are disabled, and the device resets. Subsequent writes are ignored until V<sub>CC</sub> is greater than V<sub>LKO</sub>. The system must provide the proper signals to the control pins to prevent unintentional writes when V<sub>CC</sub> is greater than V<sub>LKO</sub>.

### Write Pulse “Glitch” protection

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

### Logical Inhibit

Write cycles are inhibited by holding any one of OE# = V<sub>IL</sub>, CE# = V<sub>IH</sub>, or WE# = V<sub>IH</sub>. To initiate a write cycle, CE# and WE# must be a logical zero while OE# is a logical one. If CE#, WE#, and OE# are all logical zero (not recommended usage), it will be considered a read.

### Power-up Write Inhibit

During power-up, the device automatically resets to READ mode and locks out write cycles. Even with CE# = V<sub>IL</sub>, WE# = V<sub>IL</sub> and OE# = V<sub>IH</sub>, the device will not accept commands on the rising edge of WE#.

## COMMAND DEFINITIONS

The operations of EN39SL800 are selected by one or more commands written into the command register to perform Read/Reset Memory, Read ID, Read Block Protection, Program, Sector/Block Erase, Chip Erase, Erase Suspend and Erase Resume. Commands are made up of data sequences written at specific addresses via the command register. The sequences for the specified operation are defined in the Command Definitions table (Table 5). Incorrect addresses, incorrect data values or improper sequences will reset the device to Read Mode.

**Table 8. EN39SL800 Command Definitions**

Command Sequence		Cycles	Bus Cycles											
			1 <sup>st</sup> Cycle		2 <sup>nd</sup> Cycle		3 <sup>rd</sup> Cycle		4 <sup>th</sup> Cycle		5 <sup>th</sup> Cycle		6 <sup>th</sup> Cycle	
			Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data
Read		1	RA	RD										
Reset		1	xxx	F0										
Autoselect	Manufacturer ID	4	555	AA	2AA	55	555	90	000	7F				
									100	1C				
	Device ID	4	555	AA	2AA	55	555	90	X01	273F				
	Block Protect Verify	4	555	AA	2AA	55	555	90	(BA) X02	XX00 XX01				
Program		4	555	AA	2AA	55	555	A0	PA	PD				
Sector Erase		6	555	AA	2AA	55	555	80	555	AA	2AA	55	SA	30
Block Erase		6	555	AA	2AA	55	555	80	555	AA	2AA	55	BA	50
Chip Erase		6	555	AA	2AA	55	555	80	555	AA	2AA	55	555	10
Erase Suspend		1	xxx	B0										
Erase Resume		1	xxx	30										
CFI Query		1	55	98										

Address and Data values indicated in hex

RA = Read Address: address of the memory location to be read. This is a read cycle.

RD = Read Data: data read from location RA during Read operation. This is a read cycle.

PA = Program Address: address of the memory location to be programmed. X = Don't-Care

PD = Program Data: data to be programmed at location PA

BA = Block Address: address of the Block to be erased or verified. Address bits A18-A15 uniquely select any Block

SA = Sector Address: address of the Sector to be erased or verified. Address bits A18-A11 uniquely select any Sector

### Reading Array Data

The device is automatically set to reading array data after power up. No commands are required to retrieve data. The device is also ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

Following an Erase Suspend command, Erase Suspend mode is entered. The system can read array data using the standard read timings, with the only difference in that if it reads at an address within erase suspended sectors/blocks, the device outputs status data. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception.

The Reset command must be issued to re-enable the device for reading array data if DQ5 goes high, or while in the autoselect mode. See next section for details on Reset.

## Reset Command

Writing the reset command to the device resets the device to reading array data. Address bits are don't-care for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the device to reading array data. Once erasure begins, however, the device ignores reset commands until the operation is complete. The reset command may be written between the sequence cycles in a program command sequence before programming begins. This resets the device to reading array data (also applies to programming in Erase Suspend mode). Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to reading array data (also applies to autoselect during Erase Suspend).

If DQ5 goes high during a program or erase operation, writing the reset command returns the device to reading array data (also applies during Erase Suspend).

## Autoselect Command Sequence

The autoselect command sequence allows the host system to access the manufacturer and device codes, and determine whether or not a block is protected. The Command Definitions table shows the address and data requirements. This is an alternative to the method that requires  $V_{ID}$  on address bit A9 and is intended for PROM programmers.

Two unlock cycles followed by the autoselect command initiate the autoselect command sequence. Autoselect mode is then entered and the system may read at addresses shown in Table 4 any number of times, without needing another command sequence.

The system must write the reset command to exit the autoselect mode and return to reading array data.

## Programming Command

Programming the EN39SL800 is performed by using a four bus-cycle operation (two unlock write cycles followed by the Program Setup command and Program Data Write cycle). When the program command is executed, no additional CPU controls or timings are necessary. An internal timer terminates the program operation automatically. Address is latched on the falling edge of CE# or WE#, whichever is last; data is latched on the rising edge of CE# or WE#, whichever is first.

Programming status may be checked by sampling data on DQ7 (DATA# polling) or on DQ6 (toggle bit). When the program operation is successfully completed, the device returns to read mode and the user can read the data programmed to the device at that address. Note that data can not be programmed from a 0 to a 1. Only an erase operation can change a data from 0 to 1. When programming time limit is exceeded, DQ5 will produce a logical "1" and a Reset command can return the device to Read mode.

## Chip Erase Command

Chip erase is a six-bus-cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. The Command Definitions table shows the address and data requirements for the chip erase command sequence.

Any commands written to the chip during the Embedded Chip Erase algorithm are ignored.

The system can determine the status of the erase operation by using DQ7, DQ6, or DQ2. See “Write Operation Status” for information on these status bits. When the Embedded Erase algorithm is complete, the device returns to reading array data and addresses are no longer latched.

Flowchart 4 illustrates the algorithm for the erase operation. See the Erase/Program Operations tables in “AC Characteristics” for parameters, and to the Chip, Sector/Block Erase Operation Timings for timing waveforms.

## **Sector/Block Erase Command Sequence**

Sector/Block erase is a six bus cycle operation. The sector/block erase command sequence is initiated by writing two un-lock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the address of the sector/block to be erased, and the sector/block erase command. The Command Definitions table shows the address and data requirements for the sector/block erase command sequence.

Once the sector/block erase operation has begun, only the Erase Suspend command is valid. All other commands are ignored.

When the Embedded Erase algorithm is complete, the device returns to reading array data and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6, or DQ2. Refer to “Write Operation Status” for information on these status bits. Flowchart 4 illustrates the algorithm for the erase operation. Refer to the Erase/Program Operations tables in the “AC Characteristics” section for parameters, and to the Sector/Block Erase Operations Timing diagram for timing waveforms.

## **Erase Suspend / Resume Command**

The Erase Suspend command allows the system to interrupt a sector/block erase operation and then read data from, or program data to, any sector/block not selected for erasure. This command is valid only during the sector/block erase operation. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm. Addresses are don't-cares when writing the Erase Suspend command.

When the Erase Suspend command is written during a sector/block erase operation, the device requires a maximum of 20  $\mu$ s to suspend the erase operation.

After the erase operation has been suspended, the system can read array data from or program data to any sector/block not selected for erasure. (The device “erase suspends” all sector/blocks selected for erasure.) Normal read and write timings and command definitions apply. Reading at any address within erase-suspended sectors/blocks produces status data on DQ7–DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector/block is actively erasing or is erase-suspended. See “Write Operation Status” for information on these status bits.

After an erase-suspended program operation is complete, the system can once again read array data within non-suspended sectors/blocks. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard program operation. See “Write Operation Status” for more information. The Autoselect command is not supported during Erase Suspend Mode.

The system must write the Erase Resume command (address bits are don't-care) to exit the erase suspend mode and continue the sector/block erase operation. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the device has resumed erasing.

## WRITE OPERATION STATUS

### DQ7: DATA# Polling

The EN39SL800 provides DATA# polling on DQ7 to indicate the status of the embedded operations. The DATA# Polling feature is active during the embedded Programming, Sector/Block Erase, Chip Erase, and Erase Suspend. (See Table 6)

When the embedded Programming is in progress, an attempt to read the device will produce the complement of the data last written to DQ7. Upon the completion of the embedded Programming, an attempt to read the device will produce the true data written to DQ7. For the embedded Programming, DATA# polling is valid after the rising edge of the fourth WE# or CE# pulse in the four-cycle sequence.

When the embedded Erase is in progress, an attempt to read the device will produce a “0” at the DQ7 output. Upon the completion of the embedded Erase, the device will produce the “1” at the DQ7 output during the read cycles. For Chip Erase, the DATA# polling is valid after the rising edge of the sixth WE# or CE# pulse in the six-cycle sequence. DATA# polling is valid after the last rising edge of the WE# or CE# pulse for chip erase or sector/block erase.

DATA# Polling must be performed at any address within a sector/block that is being programmed or erased and not a protected sector/block. Otherwise, DATA# polling may give an inaccurate result if the address used is in a protected block.

Just prior to the completion of the embedded operations, DQ7 may change asynchronously when the output enable (OE#) is low. This means that the device is driving status information on DQ7 at one instant of time and valid data at the next instant of time. Depending on when the system samples the DQ7 output, it may read the status of valid data. Even if the device has completed the embedded operations and DQ7 has a valid data, the data output on DQ0-DQ6 may be still invalid. The valid data on DQ0-DQ7 will be read on the subsequent read attempts.

The flowchart for DATA# Polling (DQ7) is shown on Flowchart 5. The DATA# Polling (DQ7) timing diagram is shown in Figure 8.

### DQ6: Toggle Bit I

The EN39SL800 provides a “Toggle Bit” on DQ6 to indicate to the host system the status of the embedded programming and erase operations. (See Table 6)

During an embedded Program or Erase operation, successive attempts to read data from the device at any address (by active OE# or CE#) will result in DQ6 toggling between “zero” and “one”. Once the embedded Program or Erase operation is completed, DQ6 will stop toggling and valid data will be read on the next successive attempts. During embedded Programming, the Toggle Bit is valid after the rising edge of the fourth WE# pulse in the four-cycle sequence. During Erase operation, the Toggle Bit is valid after the rising edge of the sixth WE# pulse for sector/block erase or chip erase.

In embedded Programming, if the block being written to is protected, DQ6 will toggle for about 2  $\mu$ s, then stop toggling without the data in the block having changed. In Sector/Block Erase or Chip Erase, if all selected blocks are protected, DQ6 will toggle for about 100  $\mu$ s. The chip will then return to the read mode without changing data in all protected blocks.

The flowchart for the Toggle Bit (DQ6) is shown in Flowchart 6. The Toggle Bit timing diagram is shown in Figure 9.

### DQ5: Exceeded Timing Limits

DQ5 indicates whether the program or erase time has exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a “1.” This is a failure condition that indicates the program or erase cycle was not successfully completed. Since it is possible that DQ5 can become a 1 when the device has successfully completed its operation and has returned to read mode, the user must check again to see if the DQ6 is toggling after detecting a “1” on DQ5.

The DQ5 failure condition may appear if the system tries to program a “1” to a location that is previously programmed to “0.” **Only an erase operation can change a “0” back to a “1.”** Under this condition, the device halts the operation, and when the operation has exceeded the timing limits, DQ5 produces a “1.” Under both these conditions, the system must issue the reset command to return the device to reading array data.

### DQ3: Sector/Block Erase Timer

After writing a sector/block erase command sequence, the output on DQ3 can be used to determine whether or not an erase operation has begun. (The sector/block erase timer does not apply to the chip erase command.) When sector/block erase starts, DQ3 switches from “0” to “1.” This device does not support multiple sector/block erase command sequences so it is not very meaningful since it immediately shows as a “1” after the first 30h command. Future devices may support this feature.

### DQ2: Erase Toggle Bit II

The “Toggle Bit” on DQ2, when used with DQ6, indicates whether a particular sector/block is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector/block is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence. DQ2 toggles when the system reads at addresses within those sectors/blocks that have been selected for erasure. (The system may use either OE# or CE# to control the read cycles.) But DQ2 cannot distinguish whether the sector/block is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors/blocks are selected for erasure. Thus, both status bits are required for sector/block and mode information. Refer to the following table to compare outputs for DQ2 and DQ6.

Flowchart 6 shows the toggle bit algorithm, and the section “DQ2: Toggle Bit” explains the algorithm. See also the “DQ6: Toggle Bit I” subsection. Refer to the Toggle Bit Timings figure for the toggle bit timing diagram. The DQ2 vs. DQ6 figure shows the differences between DQ2 and DQ6 in graphical form.

### Reading Toggle Bits DQ6/DQ2

Refer to Flowchart 6 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ7–DQ0 at least twice in a row to determine whether a toggle bit is toggling. Typically, a system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ7–DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (top of Flowchart 6).

### Write Operation Status

Operation		DQ7 (note2)	DQ6	DQ5 (note1)	DQ3	DQ2 (note2)
Standard Mode	Embedded Program Algorithm	DQ7#	Toggle	0	N/A	No toggle
	Embedded Erase Algorithm	0	Toggle	0	1	Toggle
Erase Suspend Mode	Reading within Erase Suspended Sector/Block	1	No Toggle	0	N/A	Toggle
	Reading within Non-Erase Suspended Sector/Block	Data	Data	Data	Data	Data
	Erase-Suspend Program	DQ7#	Toggle	0	N/A	N/A

1. DQ5 switches to '1' when an Embedded Program or Embedded Erase operation has exceeded the maximum timing limits. See "DQ5:Exceeded Timing Limits" for more information.
2. DQ7 and DQ2 require a valid address when reading status information. Refer to the appropriate subsection for further details.

Table 9. Status Register Bits

DQ	Name	Logic Level	Definition
7	DATA# POLLING	'1'	Erase Complete or erase Sector/Block in Erase suspend
		'0'	Erase On-Going
		DQ7	Program Complete or data of non-erase Sector/Block during Erase Suspend
		DQ7#	Program On-Going
6	TOGGLE BIT	'-1-0-1-0-1-0-1-'	Erase or Program On-going
		DQ6	Read during Erase Suspend
		'-1-1-1-1-1-1-1-'	Erase Complete
5	TIME OUT BIT	'1'	Program or Erase Error
		'0'	Program or Erase On-going
3	ERASE TIME OUT BIT	'1'	Erase operation start
		'0'	Erase timeout period on-going
2	TOGGLE BIT	'-1-0-1-0-1-0-1-'	Chip Erase, Sector/Block Erase or Erase suspend on currently addressed Sector/Block. (When DQ5=1, Erase Error due to currently addressed Sector/Block. Program during Erase Suspend on-going at current address
		DQ2	Erase Suspend read on non Erase Suspend Sector/Block

**Notes:**

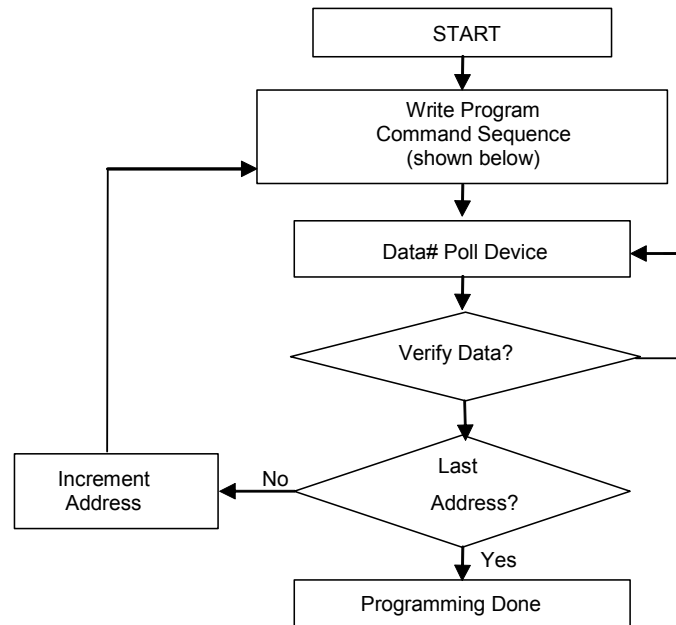

DQ7 DATA# Polling: indicates the P/E C status check during Program or Erase, and on completion before checking bits DQ5 for Program or Erase Success.

DQ6 Toggle Bit: remains at constant level when P/E operations are complete or erase suspend is acknowledged. Successive reads output complementary data on DQ6 while programming or Erase operation are on-going.

DQ5 Time Out Bit: set to "1" if failure in programming or erase

DQ3 Sector/Block Erase Command Timeout Bit: Operation has started. Only possible command is Erase suspend (ES).

DQ2 Toggle Bit: indicates the Erase status and allows identification of the erased Sector/Block

1. PA=Program Address, PD=Program Data, D<sub>OUT</sub> is the true data at the program address.
2. V<sub>CC</sub> shown in order to illustrate t<sub>VCS</sub> measurement references. It cannot occur as shown during a valid command sequence.

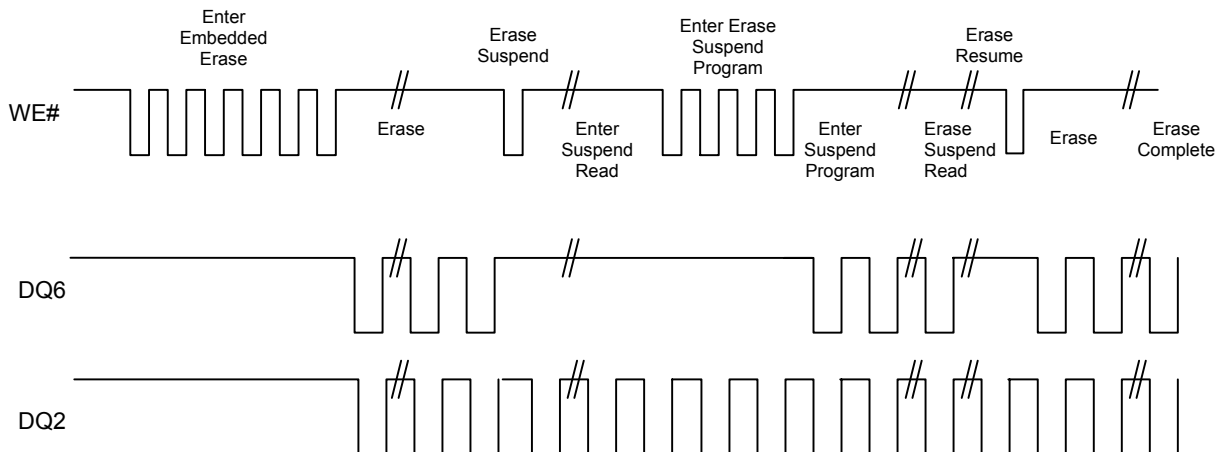

**Figure 7. AC Waveforms for /DATA Polling During Embedded Algorithm Operations**

**Notes:**

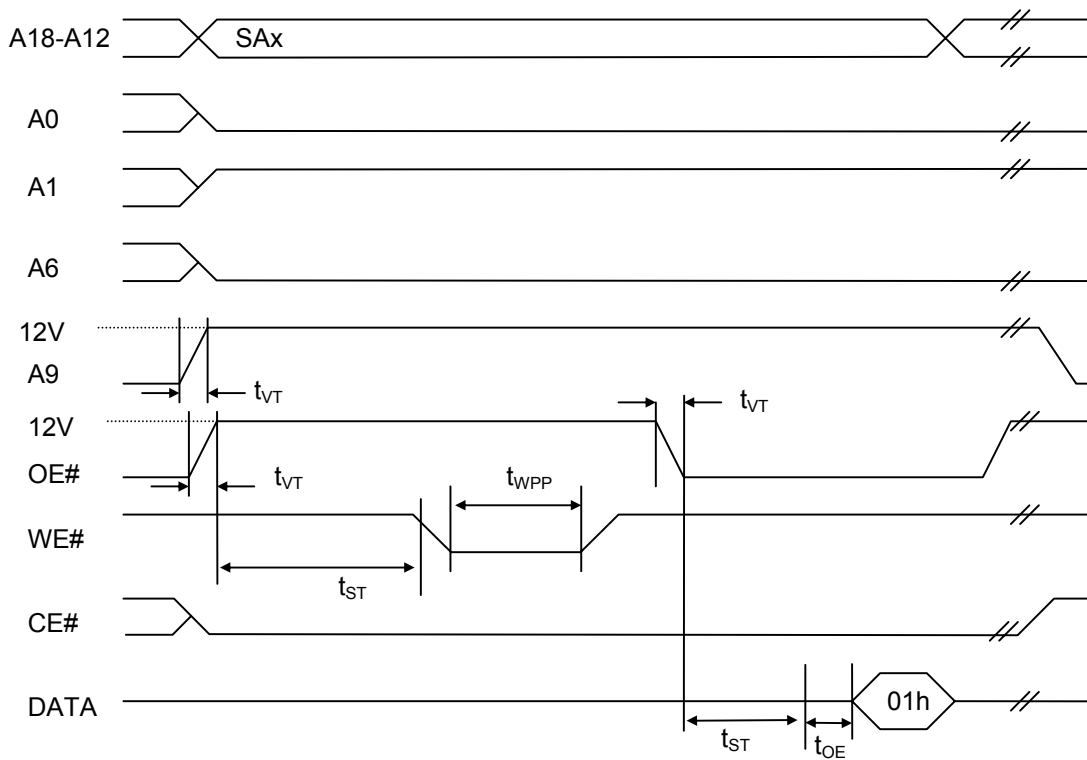

1. VA=Valid Address for reading Data# Polling status data
2. This diagram shows the first status cycle after the command sequence, the last status read cycle and the array data read cycle.

**Figure 8. AC Waveforms for Toggle Bit During Embedded Algorithm Operations**

**Figure 9. Alternate CE# Controlled Write Operation Timings**

**Notes:**

PA = address of the memory location to be programmed.  
 PD = data to be programmed at byte address.  
 VA = Valid Address for reading program or erase status  
 D<sub>out</sub> = array data read at VA

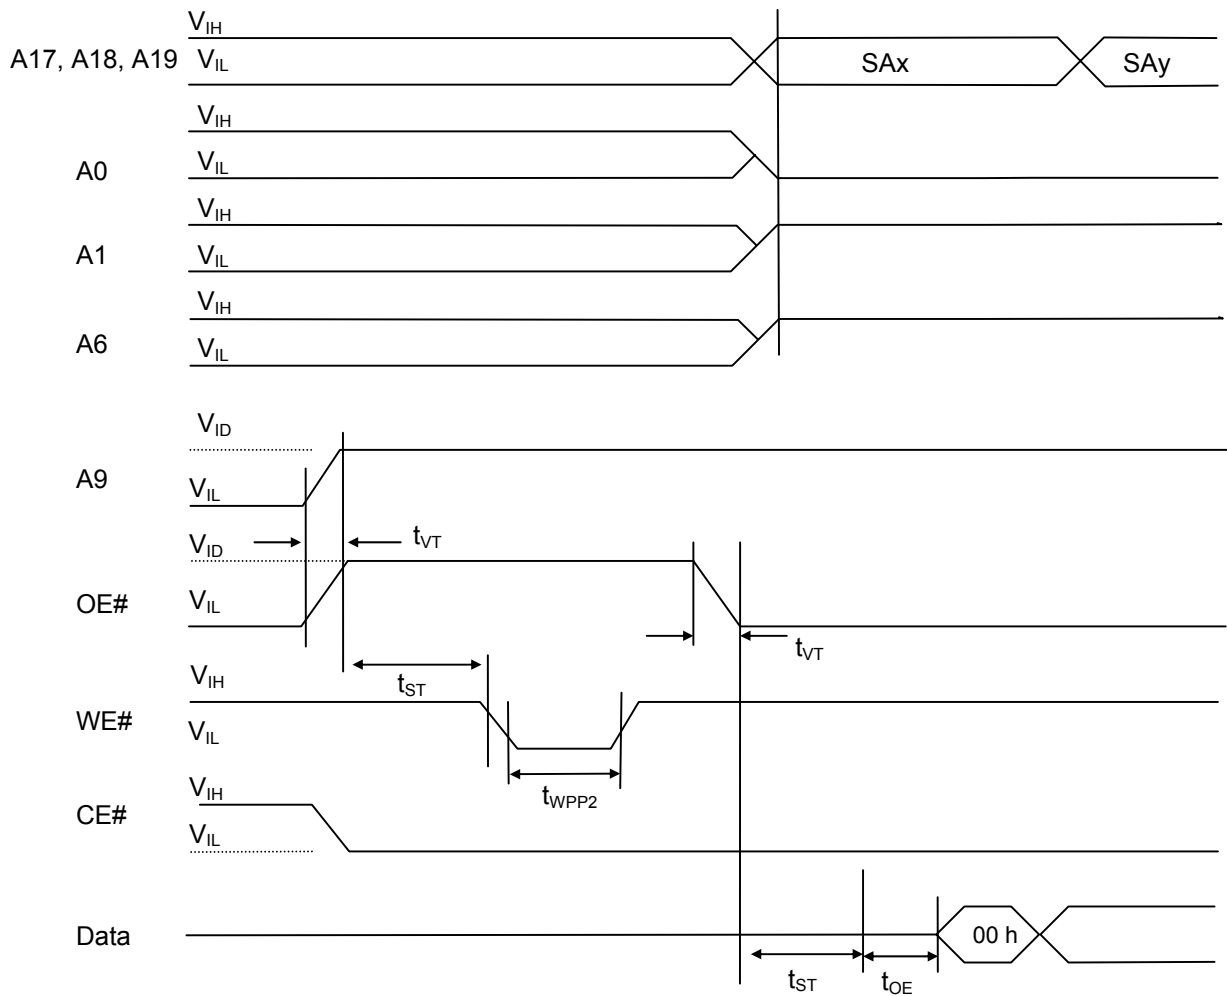

**Figure 10. DQ2 vs. DQ6**

**Figure 11. Block Protect Timing Diagram**

SAx = Block Address for initial block  
 SAy = Block Address for next block

**Notes:**

Use standard microprocessor timings for this device for read and write cycles.  
 For Block Protect, use A6=0, A1=1, A0=0.

**Figure 12. Chip Unprotect Timing Diagram**

**Notes:**

Use standard microprocessor timings for this device for read and write cycles.  
 For Chip Unprotect, use A6=1, A1=1, A0=0.

**Figure 13. 48L TFBGA 6mm x 8mm package outline**

SYMBOL	DIMENSION IN MM		
	MIN.	NOR	MAX
<b>A</b>	---	---	<b>1.30</b>
<b>A1</b>	<b>0.23</b>	<b>0.29</b>	---
<b>A2</b>	<b>0.84</b>	<b>0.91</b>	---
<b>D</b>	<b>7.90</b>	<b>8.00</b>	<b>8.10</b>
<b>E</b>	<b>5.90</b>	<b>6.00</b>	<b>6.10</b>
<b>D1</b>	---	<b>5.60</b>	---
<b>E1</b>	---	<b>4.00</b>	---
<b>e</b>	---	<b>0.80</b>	---
<b>b</b>	<b>0.35</b>	<b>0.40</b>	<b>0.45</b>

**Note : 1. Coplanarity: 0.1 mm**

**Figure 14. 48L WFBGA 4mm x 6mm package outline**

**Note : Controlling dimensions are in millimeters (mm).**

**ABSOLUTE MAXIMUM RATINGS**

Parameter		Value	Unit
Storage Temperature		-65 to +150	°C
Plastic Packages		-65 to +125	°C
Ambient Temperature With Power Applied		-55 to +125	°C
Output Short Circuit Current <sup>1</sup>		200	mA
Voltage with Respect to Ground	A9, OE# <sup>2</sup>	-0.5 to +11.0	V
	All other pins <sup>3</sup>	-0.5 to V <sub>cc</sub> +0.5	V
	V <sub>cc</sub>	-0.5 to V <sub>cc</sub> +0.5	V

**Notes:**

1. No more than one output shorted may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.
2. Minimum DC input voltage on A9 and OE# pins is -0.5V. During voltage transitions, A9 and OE# pins may undershoot V<sub>ss</sub> to -1.0V for periods of up to 50ns and to -2.0V for periods of up to 20ns. See figure below. Maximum DC input voltage on A9 and OE# is 9.0V which may overshoot to 11.0V for periods up to 20ns.
3. Minimum DC voltage on input or I/O pins is -0.5 V. During voltage transitions, inputs may undershoot V<sub>ss</sub> to -1.0V for periods of up to 50ns and to -2.0 V for periods of up to 20ns. See figure below. Maximum DC voltage on output and I/O pins is V<sub>cc</sub> + 0.5 V. During voltage transitions, outputs may overshoot to V<sub>cc</sub> + 1.5 V for periods up to 20ns. See figure below.
4. Stresses above the values so mentioned above may cause permanent damage to the device. These values are for a stress rating only and do not imply that the device should be operated at conditions up to or above these values. Exposure of the device to the maximum rating values for extended periods of time may adversely affect the device reliability.

**RECOMMENDED OPERATING RANGES<sup>1</sup>**

Parameter	Value	Unit
Ambient Operating Temperature Industrial Devices	-40 to 85	°C
Operating Supply Voltage V <sub>cc</sub>	Full Voltage Range: 1.65 to 1.95	V

1. Recommended Operating Ranges define those limits between which the functionality of the device is guaranteed.

Maximum Negative Overshoot Waveform

Maximum Positive Overshoot Waveform

## Purpose

Eon Silicon Solution Inc. (hereinafter called “Eon”) is going to provide its products’ top marking on ICs with < cFeon > from January 1st, 2009, and without any change of the part number and the compositions of the ICs. Eon is still keeping the promise of quality for all the products with the same as that of Eon delivered before. Please be advised with the change and appreciate your kindly cooperation and fully support Eon’s product family.

## Eon products’ New Top Marking

**cFeon**

### cFeon Top Marking Example:

<b>cFeon</b>
<b>Part Number: XXXX-XXX</b>
<b>Lot Number: XXXXX</b>
<b>Date Code: XXXXX</b>

## For More Information

Please contact your local sales office for additional information about Eon memory solutions.

**ORDERING INFORMATION**

**PACKAGING CONTENT**

P = RoHS compliant

**TEMPERATURE RANGE**

I = Industrial (-40°C to +85°C)

**PACKAGE**

- B = 48-Ball Thin Fine Pitch Ball Grid Array (TFBGA)  
0.8mm pitch, 6mm x 8mm package
- N = 48-Ball Very-Very-Thin-Profile Fine Pitch  
Ball Grid Array (WFBGA)  
0.5mm pitch, 4mm x 6mm package

**SPEED**

70 = 70ns

**BASE PART NUMBER**

EN = Eon Silicon Solution Inc.  
39SL = 1.8V Serial 4KByte Uniform-Sector FLASH  
800 = 8 Megabit (512K x 16)

**Revisions List**

Revision No	Description	Date
A	Initial Release	2009/02/20
B	1. Modify Table 5 addresses 13h = 0002h, 14h = 0000h and 15h = 0040h on page 12. 2. Update Table 12, 13 on page 31 and 32.	2009/03/03
C	1. Correct typo 15→5 mA typical active read current in page 1. 2. Correct typo t <sub>BUSY</sub> Min→Max in Page 31.	2009/03/24
D	To modify Table 10, Icc1 active read current (max.) from 6mA to 10mA on page 26	2009/05/13
E	1. Modify TFBGA ball diagram (BYTE#, RESET# and RY/BY# pins are changed to NC status) 2. Removal of WPGA 5mm x 6mm package definition 3. addition of TSOP (type 1) package information	2009/06/08
F	1. Removal of all of 90ns descriptions 2. modify the max sector erase time to 0.4s 3. adding byte / word programming maximum time	2009/06/15
G	1. Remove the BYTE#, RESET# and RY/BY# functions and TSOP (type 1) package information. 2. Modify the description of Block Protection and Chip Unprotection on page 10, 24, 25, 38 and 39.	2009/08/18
H	Update Table 4.DEVICE IDENTIFICATION (Autoselect Codes) on page 8.	2011/02/14
I	Add Support JEDEC Common Flash Interface (CFI) information on page 1.	2012/03/19
