

## Features

- Audio Processor
  - Proprietary Digital Signal Processor
  - MP3 and WMA Decoders
  - WAV PCM and ADPCM Decoder/Coder with AGC
  - JPEG decoder
  - Video Animation (MTV up to 16fps)
- Audio Codec
  - 16-bit Stereo D/A Converters<sup>(3)</sup>
  - Headphone Amplifier with Analog Volume Control<sup>(3)</sup>
  - Microphone Pre-Amplifier with Bias Control
  - 16-bit Mono A/D Converter: Microphone or Line Inputs Recording
  - Stereo Lines Input for FM Playback or Mono Recording
  - 3-band EQ and Bass Boost and 3D Sound Effects
  - Graphical EQ
- Digital Audio DAC Interface
  - PCM / I<sup>2</sup>S Format Compatible
- USB Rev 2.0 Controller
  - 7 Endpoints, Multiple Enumeration
  - High Speed Mode (480 Mbps)
  - Full Speed Mode (12 Mbps)
  - On The Go Full Speed Mode
- File Management
  - Fat 12, 16, 32 Management
  - Multiple Drive Management: Nand Flash, Card, U-Disk...
  - Multiple Folders and Sub-Folders (user defined)
  - Multiple File Read and Write
  - Playlist and Lyrics Support
- Data Flow Controller
  - 16-bit Multimedia Bus with 2 DMA Channels for high speed transfer with USB
- Nand Flash Controller
  - Multiple Nand as 1 Drive, Support All Page Size
  - Read up to 10MB/s, Write up to 8MB/s
  - Built-in ECC and Hardware Write Protection
- MultiMediaCard<sup>®</sup> Controller
  - MultiMediaCard 1-bit / 4-bits Modes (V4 compatible)
  - Secure Digital Card 1-bit / 4-bit Modes
- Man Machine Interface
  - Glueless Generic LCD Interface
  - Keyboard Interface
  - FM Tuner Input and Control including RDS
  - PSI I80 Slave Interface (EBI Compatible) up to 6Mbytes/s
  - SPI Master and Slave Modes
  - Full Duplex UART with Baud Rate Generator up to 6 Mbit/s (Rx, Tx, RTS, CTS)
- Control Processor
  - Enhanced 8-bit MCU C51 Core ( $F_{MAX} = 24$  MHz)
  - 64K Bytes of Internal RAM for application code and data
  - Boot ROM Memory: Secured Nand Flash Boot Strap (standard), USB Boot Loader
  - Two 16-bit Timers/Counters: Hardware Watchdog Timer
  - In-System and In-Application Programming
- Power Management
  - 1.8V 40 mA Single AAA or AA Battery Powered<sup>(4)</sup>
  - Direct USB  $V_{BUS}$  Supply
  - 3V or 1.8V - 50 mA Regulator Output
  - Battery Voltage Monitoring
  - Power-on Reset, Idle, Power-Down, Power-Off Modes
  - Software Programmable MCU Clock
- Operating Conditions
  - Supply 1.8V to 5V for all Product range, plus 0.9V to 1.8V<sup>(4)</sup>

## Single-Chip Digital Audio Decoder - Encoder with USB 2.0 Interface

**AT85C51SND3B**

**Preliminary**

7632D-MP3-01/07

- 25 mA Typical Operating at 25°C (estimation to be confirmed)
- Temperature Range: -40°C to +85°C

- Packages

- LQFP100, BGA100, Dice

- Notes:
1. See Ordering Information
  2. AT85C51SND3B1 & AT85C51SND3B2 only
  3. AT85C51SND3B2 only

## Description

Digital Music Players, Mobile Phones need ready to use low-cost solutions for very fast time to market. The AT85C51SND3B with associated firmware embeds in a single chip all features, hardware and software, for Digital Music Players, Mobile Phones and Industrial or Toys applications: MP3 decoder, WMA decoder, Display interface, serial interface, parallel interface, USB high speed and USB host.

Close to a plug and play solution for most applications, the AT85C51SND3B drastically reduces system development for the best time to market. The AT85C51SND3B handles full file system management with Nand Flash and Flash Cards, including full detection and operation of a thumb drive. The AT85C51SND3Bx is used either as a master controller, or as a slave controller interfacing easily with most of the base-band or host processors available on the market.

The AT85C51SND3B includes Power Management with: 5V USB  $V_{BUS}$  direct supply, 2.7V to 3.6V supply, 1.8V supply or alkaline battery supply (0.9V to 1.8V). External Nand Flash or Flash Card can be supplied by the AT85C51SND3B at 1.8V or 3V.

The AT85C51SND3B supports many applications including: mobile phones, music players, portable navigation, car audio, music in shopping centers, applications including MMC/SD Flash Cards in Industrial applications.

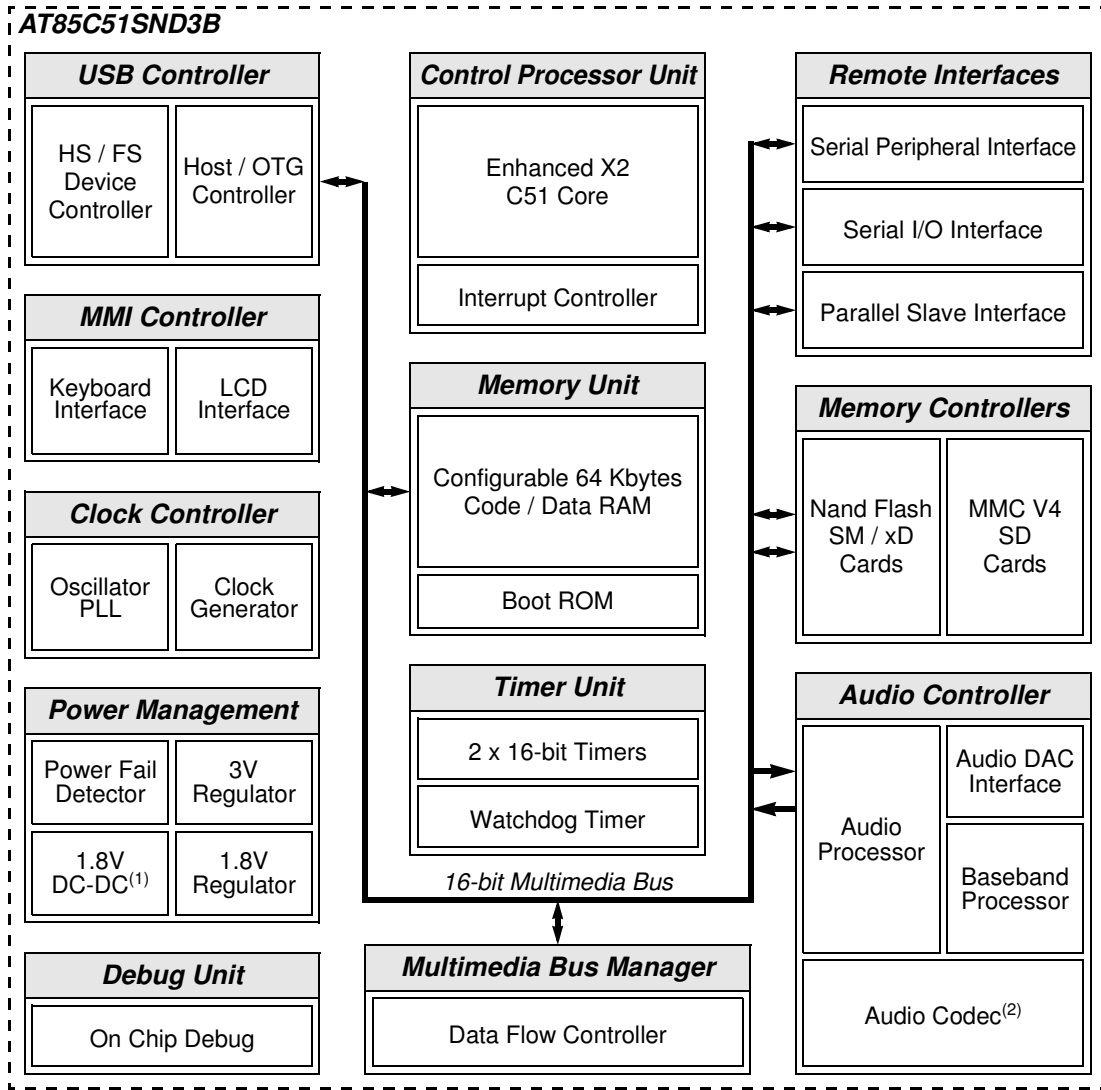

To facilitate custom applications with the AT85C51SND3B, a development kit AT85DVK-07 and a reference design AT85RFD-07 are available with hardware and firmware database.

## Key Features

- Firmware to support
  - MP3
  - WMA
  - ADPCM/WAV voice or line recording
  - JPEG Decoder
- Audio Codec
  - Internal DAC
  - FM inputs
- Memory Support
  - Up to 4x Nand-Flash
  - SD/MMC cards
- USB
  - High Speed, Full Speed
  - OTG (reduced Host)

# Block Diagram

Figure 1. AT85C51SND3B Block Diagram

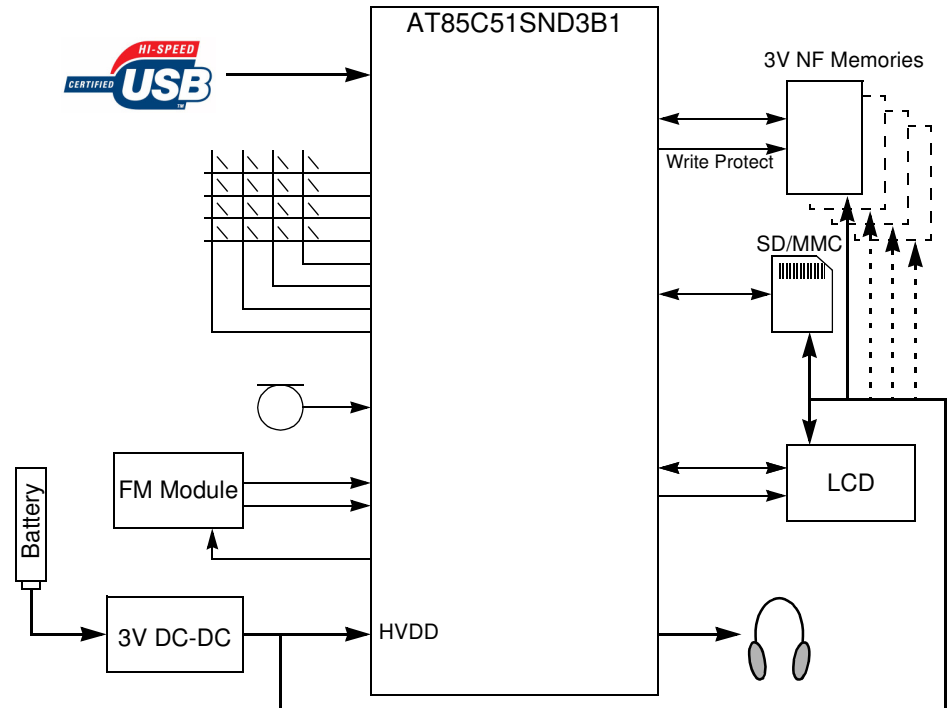

- Notes: 1. AT85C51SND3B2 only  
 2. AT85C51SND3B1 & AT85C51SND3B2 only

## Application Information

The AT85C51SND3B derivatives allow design of 2 typical applications which differentiate by the power supply voltage:

- The Very Low Voltage System  
The player operates at 1.8V and allows very low power consumption.
- The Low Voltage System  
The player operates at 3V and allows low power consumption.

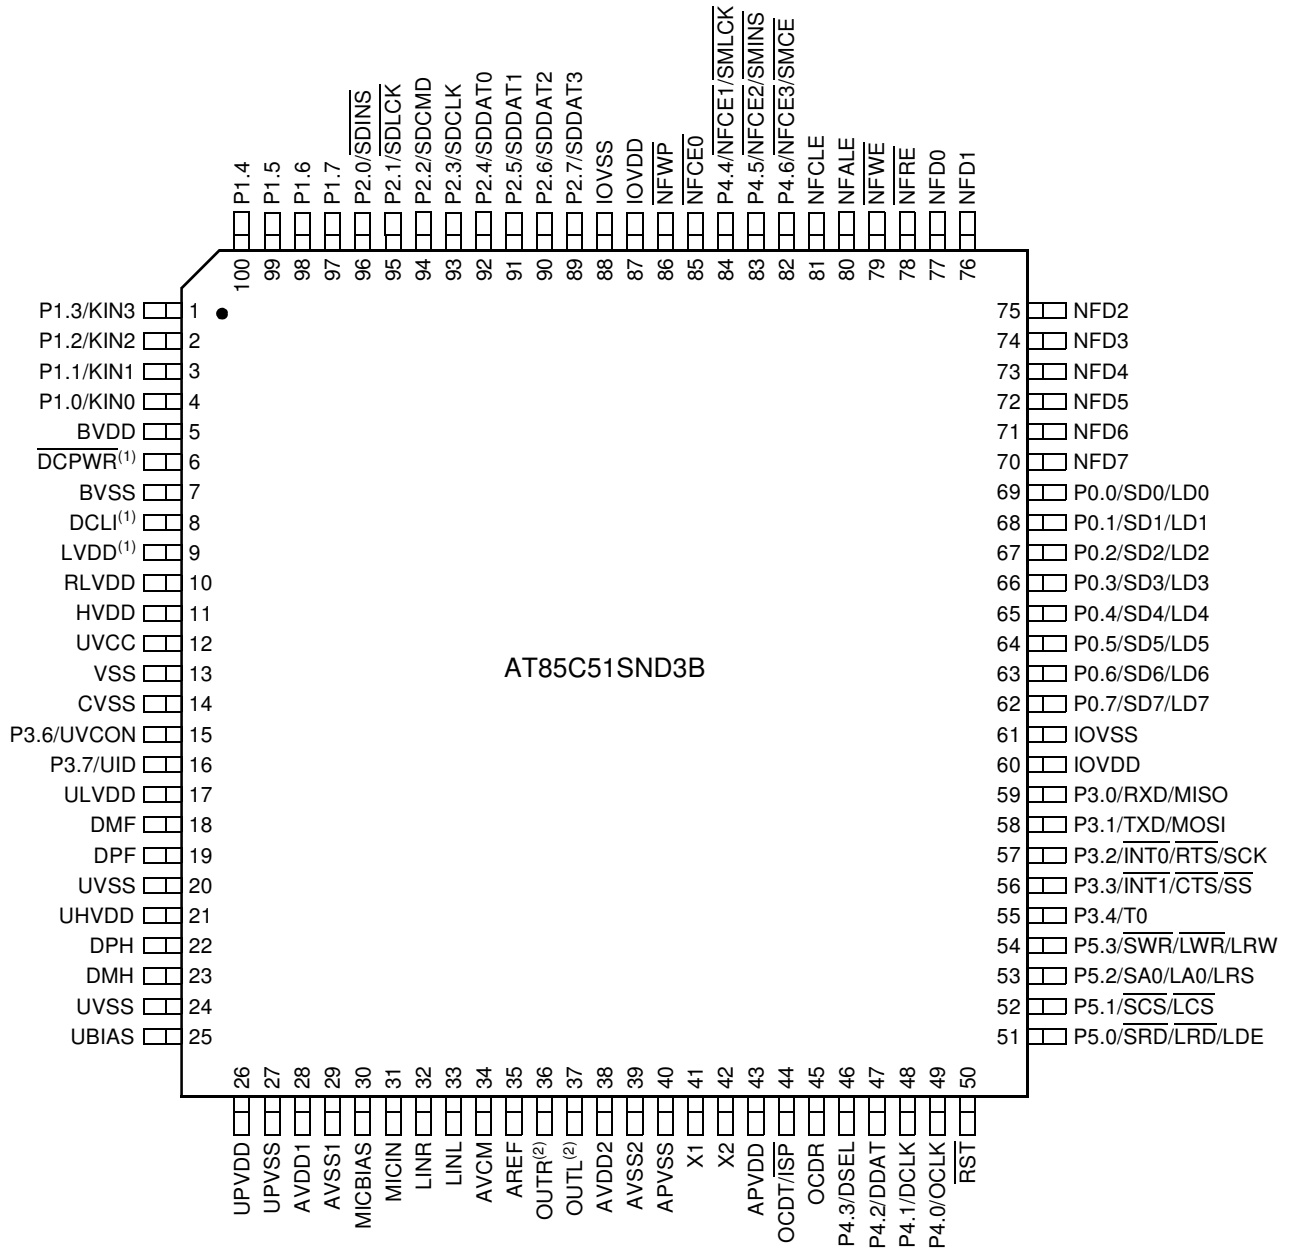

**Figure 2.** Typical Low Voltage 3V Application

# Pin Description

## Pinouts

Figure 3. AT85C51SND3B 100-pin QFP Package

- Notes:
1. Leave these pins unconnected for AT85C51SND3B0 & AT85C51SND3B1 products
  2. Leave these pins unconnected for AT85C51SND3B0 product

## Signals Description

### System

**Table 1.** System Signal Description

Signal Name	Type	Description	Alternate Function
$\overline{\text{RST}}$	I/O	<p><b>Reset Input</b> Holding this pin low for 64 oscillator periods while the oscillator is running resets the device. The Port pins are driven to their reset conditions when a voltage lower than <math>V_{IL}</math> is applied, whether or not the oscillator is running.</p> <p>This pin has an internal pull-up resistor (<math>R_{RST}</math>) which allows the device to be reset by connecting a capacitor between this pin and <math>V_{SS}</math>.</p> <p>Asserting <math>\overline{\text{RST}}</math> when the chip is in Idle mode or Power-Down mode returns the chip to normal operation.</p> <p>In order to reset external components connected to the <math>\overline{\text{RST}}</math> line a low level 96-clock period pulse is generated when the watchdog timer reaches its time-out period.</p>	-
$\overline{\text{ISP}}$	I	<p><b>In System Programming</b> Assert this pin during reset phase to enter the in system programming mode.</p>	OCDT

**Table 2.** Ports Signal Description

Signal Name	Type	Description	Alternate Function
P0.7:0	I/O	<p><b>Port 0</b> P0 is an 8-bit bidirectional I/O port with internal pull-ups.</p>	LD7:0
P1.7:0	I/O	<p><b>Port 1</b> P1 is an 8-bit bidirectional I/O port with internal pull-ups.</p>	KIN3:0
P2.7:0	I/O	<p><b>Port 2</b> P2 is an 8-bit bidirectional I/O port with internal pull-ups.</p>	$\overline{\text{SDINS}}$ $\overline{\text{SDLCK}}$ $\overline{\text{SDCMD}}$ $\overline{\text{SDCLK}}$ $\overline{\text{SDDAT3:0}}$
P3.4:0 P3.7:6	I/O	<p><b>Port 3</b> P3 is a 7-bit bidirectional I/O port with internal pull-ups.</p>	RXD MISO TXD MOSI $\overline{\text{INT0}}$ RTS SCK $\overline{\text{INT1}}$ CTS SS T0 UVCON UID

Signal Name	Type	Description	Alternate Function
P4.6:0	I/O	<b>Port 4</b> P4 is a 7-bit bidirectional I/O port with internal pull-ups.	OCLK DCLK DDAT DSEL NFCE1/SMLCK NFCE2/SMINS NFCE3/SMCE
P5.3:0	I/O	<b>Port 5</b> P5 is a 4-bit bidirectional I/O port with internal pull-ups.	$\overline{\text{LRD/LDE}}$ SDR $\overline{\text{LCS}}$ SCS LA0/LRS SA0 $\overline{\text{LWR/LRW}}$ SWR

**Table 3.** Timer 0 and Timer 1 Signal Description

Signal Name	Type	Description	Alternate Function
$\overline{\text{INT0}}$	I	<b>Timer 0 Gate Input</b> $\overline{\text{INT0}}$ serves as external run control for timer 0, when selected by GATE0 bit in TCON register. <b>External Interrupt 0</b> $\overline{\text{INT0}}$ input sets IE0 in the TCON register. If bit IT0 in this register is set, bit IE0 is set by a falling edge on $\overline{\text{INT0}}$ . If bit IT0 is cleared, bit IE0 is set by a low level on $\overline{\text{INT0}}$ .	P3.2 RTS SCK
$\overline{\text{INT1}}$	I	<b>Timer 1 Gate Input</b> $\overline{\text{INT1}}$ serves as external run control for timer 1, when selected by GATE1 bit in TCON register. <b>External Interrupt 1</b> $\overline{\text{INT1}}$ input sets IE1 in the TCON register. If bit IT1 in this register is set, bit IE1 is set by a falling edge on $\overline{\text{INT1}}$ . If bit IT1 is cleared, bit IE1 is set by a low level on $\overline{\text{INT1}}$ .	P3.3 CTS SS
T0	I	<b>Timer 0 External Clock Input</b> When timer 0 operates as a counter, a falling edge on the T0 pin increments the count.	P3.4

## Clock Controller

**Table 4.** Clock Signal Description

Signal Name	Type	Description	Alternate Function
X1	I	<b>Input of the on-chip inverting oscillator amplifier</b> To use the internal oscillator, a crystal/resonator circuit is connected to this pin. If an external oscillator is used, its output is connected to this pin. X1 is the clock source for internal timing.	-
X2	O	<b>Output of the on-chip inverting oscillator amplifier</b> To use the internal oscillator, a crystal/resonator circuit is connected to this pin. If an external oscillator is used, leave X2 unconnected.	-
UPVDD	PWR	<b>USB PLL Supply voltage</b> Connect this pin to LVDD pin.	-
UPVSS	GND	<b>USB PLL Circuit Ground</b> Connect this pin to LVSS pin.	-
APVDD	PWR	<b>Audio PLL / Oscillator Supply voltage</b> Connect this pin to LVDD pin.	-
APVSS	GND	<b>Audio PLL / Oscillator Circuit Ground</b> Connect this pin to LVSS pin.	-

## Memory Controllers

**Table 5.** Secure Digital Card / MultiMediaCard Controller Signal Description

Signal Name	Type	Description	Alternate Function
SDCLK	O	<b>SD/MMC Clock</b> Data or command clock transfer.	P2.3
SDCMD	I/O	<b>SD/MMC Command Line</b> Bidirectional command line used for commands and responses transfer.	P2.2
SDDAT3:0	I/O	<b>SD/MMC Data Lines</b> Bidirectional data lines. In 1-bit mode configuration SDDAT0 is the DAT signal and SDDAT3:1 are not used and can be reused as I/O ports.	P2.7:4
$\overline{\text{SDINS}}$	I	<b>SD/MMC Card Insertion Signal</b> $\overline{\text{SDINS}}$ is the card presence signal. A low level on this input indicates the card is present in its slot. Note: This signal is generated by the SD/MMC card connector.	P2.0
$\overline{\text{SDLCK}}$	I	<b>SD Card Write Lock Signal</b> $\overline{\text{SDLCK}}$ is the SD Card write protected input. A low level on this pin indicates the card is write protected. Note: This signal is generated by the SD/MMC card connector.	P2.1

**Table 6.** Nand Flash / SmartMedia Card Controller Signal Description

Signal Name	Type	Description	Alternate Function
NFD7:0	I/O	<b>Memory Data Bus</b> 8-bit bidirectional data bus.	-
NFALE	O	<b>Address Latch Enable Signal</b> Asserted high during address write cycle.	-

Signal Name	Type	Description	Alternate Function
NFCLE	O	<b>Command Latch Enable Signal</b> Asserted high during command write cycle.	-
$\overline{\text{NFRE}}$	O	<b>Read Enable Signal</b> Read signal asserted low during NF/SMC read operation.	-
$\overline{\text{NFWE}}$	O	<b>Write Enable Signal</b> Write signal asserted low during NF/SMC write operation.	-
$\overline{\text{NFCE0}}$	O	<b>Nand Flash 0 Chip Enable</b> $\overline{\text{NFCE0}}$ is active low and is asserted by the nand flash controller each time it makes access to the device 0.	-
$\overline{\text{NFCE1}}$ $\overline{\text{SMLCK}}$	O I	<b>Nand Flash 1 Chip Enable</b> $\overline{\text{NFCE1}}$ is active low and is asserted by the nand flash controller each time it makes access to the selected device. <b>SmartMediaCard/xD-Picture Card Write Lock Signal</b> $\overline{\text{SMLCK}}$ is the card write protected input. A low level on this pin indicates the card is write protected. Note: When used as $\overline{\text{SMLCK}}$ input, pad has internal pull-up.	P4.4
$\overline{\text{NFCE2}}$ $\overline{\text{SMINS}}$	O I	<b>Nand Flash 2 Chip Enable</b> $\overline{\text{NFCE2}}$ is active low and is asserted by the nand flash controller each time it makes access to the selected device. <b>SmartMediaCard/xD-Picture Card Insertion Signal</b> $\overline{\text{SMINS}}$ is the card presence signal. A low level on this input indicates the card is present in its slot. Note: When used as $\overline{\text{SMINS}}$ input, pad has internal pull-up.	P4.5
$\overline{\text{NFCE3}}$ $\overline{\text{SMCE}}$	O O	<b>Nand Flash 3 Chip Enable</b> $\overline{\text{NFCE3}}$ is active low and is asserted by the nand flash controller each time it makes access to the selected device. <b>SmartMediaCard/xD-Picture Card Chip Enable</b> $\overline{\text{SMCE}}$ is active low and is asserted by the nand flash controller each time it makes access to the card.	P4.6
$\overline{\text{NFWP}}$	O	<b>Write Protect Signal</b> $\overline{\text{NFWP}}$ is the Nand Flash / SmartMediaCard/xD-Picture Card write protect signal. This signal is active low and is set to low during reset in order to protect the memory against parasitic writes.	-

## USB Controller

**Table 7.** USB Controller Signal Description

Signal Name	Type	Description	Alternate Function
DPF	I/O	<b>USB Full Speed Positive Data Upstream Port</b>	-
DMF	I/O	<b>USB Full Speed Minus Data Upstream Port</b>	-
DPH	I/O	<b>USB High Speed Plus Data Upstream Port</b>	-
DMH	I/O	<b>USB High Speed Minus Data Upstream Port</b>	-
UVCON	O	<b>USB VBUS Control line</b> UVCON is used to control the external VBUS power supply ON or OFF. Note: This output is requested for OTG mode.	P3.6

Signal Name	Type	Description	Alternate Function
UID	I	<b>USB OTG Identifier Input</b> This pin monitors the function of the OTG device. Note: This input is requested for OTG mode.	P3.7
UVCC	PWR	<b>USB Supply Voltage</b> Connect this pin to USB $V_{BUS}$ power line.	-
ULVDD	PWR	<b>USB Pad Low Voltage</b> Connect this pin to LVDD pin.	-
UHVDD	PWR	<b>USB Pad High Voltage</b> Connect this pin to HVDD pin.	-
UVSS	GND	<b>USB Ground</b>	-
UBIAS	O	<b>USB Bias</b> Connect this pin to external resistor and capacitor.	

## Audio Processor

**Table 8.** I2S Output Description

Signal Name	Type	Description	Alternate Function
OCLK	O	<b>Over-sampling Clock Line</b>	P4.0
DCLK	O	<b>Data Clock Line</b>	P4.1
DDAT	O	<b>Data Lines</b>	P4.2
DSEL	O	<b>Data Channel Selection Line</b>	P4.3

**Table 9.** Audio Codec Description

Signal Name	Type	Description	Alternate Function
LINR	I	<b>Right Channel Analog Input</b>	-
LINL	I	<b>Left Channel Analog Input</b>	-
MICIN	I	<b>Electret Microphone Analog Input</b>	-
MICBIAS	O	<b>Electret Microphone Bias Output</b>	-
OUTR	O	<b>Right Channel Output</b> Do not connect on AT85C51SND3B0 product	-
OUTL	O	<b>Left Channel Output</b> Do not connect on AT85C51SND3B0 product	-
AVCM	I	<b>Analog Common Mode Voltage</b> Connect this pin to external decoupling capacitor.	-
AREF	O	<b>Analog Reference Voltage</b> Connect this pin to external decoupling capacitor.	-
AVDD1	PWR	<b>Analog Power Supply 1</b> Connect this pin to LVDD pin.	-
AVSS1	GND	<b>Analog Ground 1</b> Connect this pin to LVSS pin.	-

Signal Name	Type	Description	Alternate Function
AVDD2	PWR	<b>Analog Power Supply 2</b> Low Voltage system: connect this pin to LVDD pin. High voltage system: connect this pin to external +3V power supply.	-
AVSS2	GND	<b>Analog Ground 2</b> Low Voltage system: connect this pin to LVSS pin. High voltage system: connect this pin to external +3V ground.	-

## Parallel Slave Interface

**Table 10.** PSI Signal Description

Signal Name	Type	Description	Alternate Function
SD7:0	I/O	<b>Slave Data Bus</b> 8-bit bidirectional data bus.	P0.7:0 LD7:0
$\overline{\text{SRD}}$	I	<b>Slave Read Signal</b> Read signal asserted low during external host read operation.	P5.0 $\overline{\text{LRD/LDE}}$
$\overline{\text{SWR}}$	I	<b>Slave Write Signal</b> Write signal asserted low during external host write operation.	P5.3 $\overline{\text{LWR/LRW}}$
$\overline{\text{SCS}}$	I	<b>Slave Chip Select</b> Select signal asserted low during external host read or write operation.	P5.1 $\overline{\text{LCS}}$
SA0	I	<b>Slave Address Bit 0</b> Address signal asserted during external host read or write operation.	P5.2 LA0/LRS

## Serial Interfaces

**Table 11.** SPI Controller Signal Description

Signal Name	Type	Description	Alternate Function
MISO	I/O	<b>SPI Master Input Slave Output Data Line</b> When in master mode, MISO receives data from the slave peripheral. When in slave mode, MISO outputs data to the master controller.	P3.0 RXD
MOSI	I/O	<b>SPI Master Output Slave Input Data Line</b> When in master mode, MOSI outputs data to the slave peripheral. When in slave mode, MOSI receives data from the master controller.	P3.1 TXD
SCK	I/O	<b>SPI Clock Line</b> When in master mode, SCK outputs clock to the slave peripheral. When in slave mode, SCK receives clock from the master controller.	P3.2 $\overline{\text{INT0}}$ $\overline{\text{RTS}}$
$\overline{\text{SS}}$	I	<b>SPI Slave Select Line</b> When in controlled slave mode, $\overline{\text{SS}}$ enables the slave mode.	P3.3 $\overline{\text{INT1}}$ $\overline{\text{CTS}}$

**Table 12.** SIO Signal Description

Signal Name	Type	Description	Alternate Function
RXD	I/O	<b>Receive Serial Data</b> RXD sends and receives data in serial I/O mode 0 and receives data in serial I/O modes 1, 2 and 3.	P3.0 MISO

Signal Name	Type	Description	Alternate Function
TXD	O	<b>Transmit Serial Data</b> TXD outputs the shift clock in serial I/O mode 0 and transmits data in serial I/O modes 1, 2 and 3.	P3.1 MOSI
$\overline{\text{RTS}}$	O	<b>Request To Send Hardware Handshake Line</b> Asserted low by hardware when SIO is ready to receive data.	P3.2 $\overline{\text{INT0}}$ SCK
$\overline{\text{CTS}}$	I	<b>Clear To Send Hardware Handshake Line</b> Asserted low by external hardware when SIO is allowed to send data.	P3.3 $\overline{\text{INT1}}$ $\overline{\text{SS}}$

## MMI Interface

**Table 13.** Keypad Controller Signal Description

Signal Name	Type	Description	Alternate Function
KIN3:0	I	<b>Keypad Input lines</b> Holding one of these pins high or low for 24 oscillator periods triggers a keypad interrupt.	P1.3:0

**Table 14.** LCD Interface Signal Description

Signal Name	Type	Description	Alternate Function
LD7:0	I/O	<b>Display Data Bus</b> 8-bit bidirectional data bus.	P0.7:0 SD7:0
$\overline{\text{LRD/LDE}}$	O	<b>Read Signal/Enable Signal</b> 8080: Read signal asserted low during display read access. 6800: Enable signal asserted high during display access.	P5.0 $\overline{\text{SRD}}$
$\overline{\text{LWR/LRW}}$	O	<b>Write Signal/Read Write Signal</b> 8080: Write signal asserted low during display write access. 6800: Read/Write signal asserted low/high during display read/write access	P5.3 $\overline{\text{SWR}}$
$\overline{\text{LCS}}$	O	<b>Display Chip Select</b> Select signal asserted low during display access.	P5.1 $\overline{\text{SCS}}$
LA0/LRS	O	<b>Display Address Bit 0/Register Select</b> Address signal asserted during display access.	P5.2 SA0

## Power Management

**Table 15.** Power Signal Description

Signal Name	Type	Description	Alternate Function
$\overline{\text{DCPWR}}$	I	<b>DC-DC Power ON Input</b> Connect $\overline{\text{DCPWR}}$ to $V_{SS}$ to start the DC-DC converter.	-
DCLI	PWR	<b>DC-DC Inductance Input</b> Connect low ESR inductance to DCLI and BVDD.	
BVDD	PWR	<b>Battery Supply Voltage</b> Connect this pin to the positive pin of the battery.	-

Signal Name	Type	Description	Alternate Function
BVSS	GND	<b>Battery Ground</b> Connect this pin to the negative pin of the battery.	-
LVDD	PWR	<b>Low Voltage DC-DC Power Supply output</b> This pin outputs +1.8V typ. from internal DC-DC (battery powered).	-
RLVDD	PWR	<b>Low Voltage Regulator Power Supply Output</b> This pin outputs +1.8V typ. from internal regulator (USB powered or +3V external power supply). Connect this pin to LVDD incase of internal DC-DC usage.	-
HVDD	PWR	<b>High Voltage Power Supply</b> This pin outputs +3V typ. from internal regulator (USB powered). Connect this pin to +3V external power supply.	-
VSS	GND	<b>Power Ground</b> Connect this pin to the system ground.	-
CVSS	GND	<b>Core Ground</b> Connect this pin to VSS pin.	-
IOVDD	PWR	<b>Input/Output Supply voltage</b> Connect this pin to LVDD or HVDD pin.	-
IOVSS	GND	<b>Input/Output Circuit Ground</b> Connect this pin to VSS pin.	-

## OCD Interface

**Table 16.** OCD Signal Description

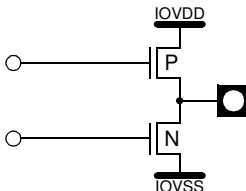

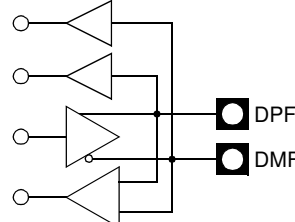

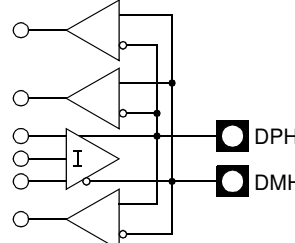

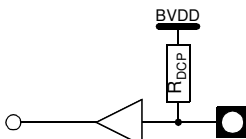

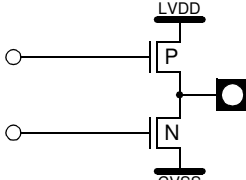

Signal Name	Type	Description	Alternate Function
OCDR	I	<b>On Chip Debug Receive Input</b> OCDR receives data.	-
OCDT	I/O	<b>On Chip Debug Transmit Output</b> OCDT transmits data.	ISP

  3. AT85C51SND3B1 & AT85C51SND3B2 only

## Power Management

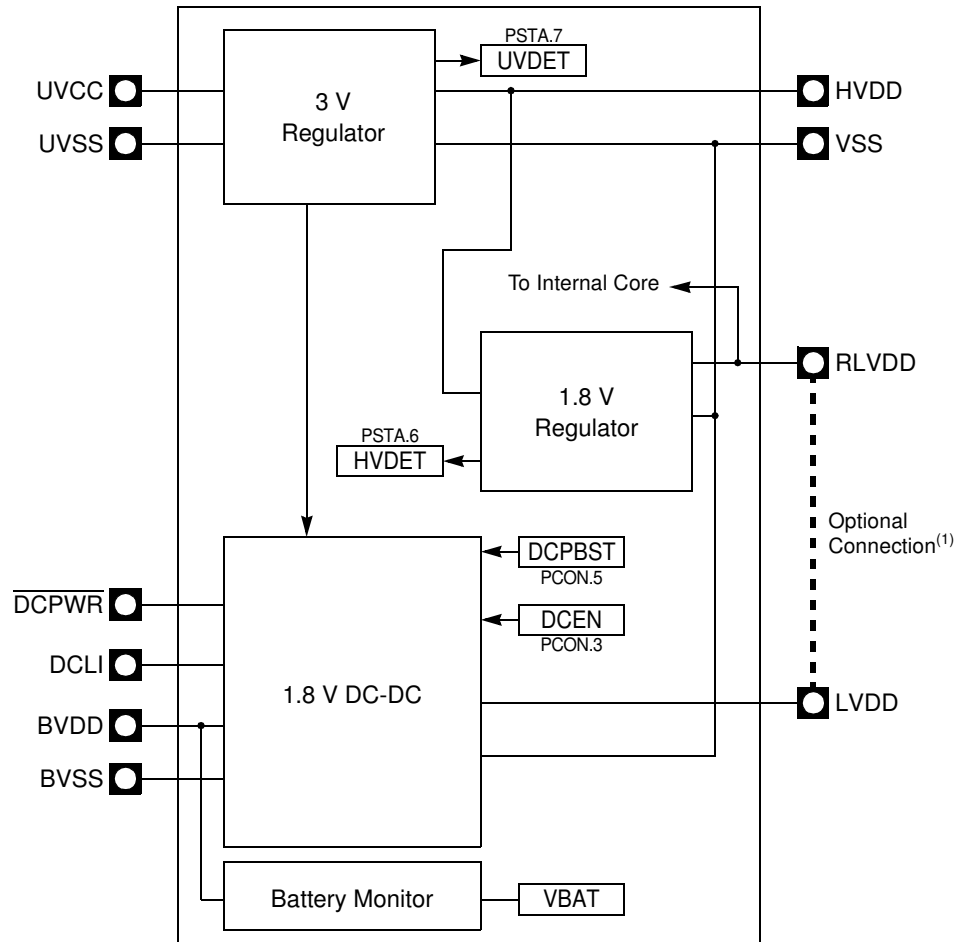

The Power Management of AT85C51SND3B derivatives implements all the internal power circuitry (regulators, links...) as well as power failure detector and reset circuitry.

## Power Supply

The AT85C51SND3B2 embeds the regulators and a DC to DC step-up convertor to be able to operate from either USB power supply (5V nominal) or from a single cell battery such as AAA battery.

The AT85C51SND3B0 and AT85C51SND3B1 embed the regulators to be able to operate from either USB power supply (5V nominal) or from an external 3 volts supply.

**Figure 5.** Power Supply Diagram

Note: 1. External connection mandatory when 1.8V DC-DC is used.

## Regulators

The high voltage regulator supplies power to the external devices through HVDD power pin. Its nominal voltage output is 3V.

The low voltage regulator supplies power to the internal device and external devices through RLVDD power pin. Its nominal voltage output is 1.8V.

Figure 6 shows how to connect external components, capacitors value along with power characteristics are specified in the section "DC characteristics".

Schematic

**Figure 6. Regulator Connection**

Note: Depending on power supply scheme,  $C_{LV}$  may replace  $C_{DC}$  capacitor (see Figure 8).

**Low Voltage DC-DC in AT85C51SND3B2**

The low voltage output DC-DC converter supplies power to the internal device and external devices through LVDD power pin. It operates from a single AAA battery. Its nominal voltage output is 1.8V.

DC-DC Start-Up

DC-DC start-up is done by asserting the  $\overline{DCPWR}$  input until the voltage reaches its nominal value (see Section "Power Fail Detector") and firmware starts execution and sets the DCEN bit in PCON to maintain the DC-DC enabled.  $\overline{DCPWR}$  input can then be released. As shown in Figure 8  $\overline{DCPWR}$  input is asserted by pressing a key connected to BVSS.

**Figure 7. DC-DC Start-Up Phase**

DC-DC Shut-Down

DC-DC shut-down is done by two different ways:

- Clearing the DCEN bit while  $\overline{DCPWR}$  pin is de-asserted
- Detecting the presence of an internal or external 3V supply, e.g. when the device is connected to USB, DC-DC is disabled to save battery power<sup>(1)</sup>.

Note: 1. If DCEN bit is left set, the DC-DC will restart as soon as the USB power supply disappears.

DC-DC Connection

Figure 8 shows how to connect external components, inductance and components value along with power characteristics are specified in the section "DC characteristics".

**Figure 8. Battery DC-DC Connection**

Note: Depending on power supply scheme,  $C_{DC1}$  may replace  $C_{LV}$  capacitor (see Figure 6).

## Battery Voltage Monitor

The battery voltage monitor is a 5-bit / 50 mV resolution A to D converter with fixed conversion range as detailed in Table 18.

**Table 18.** Battery Voltage Value

VB4:0	Battery Voltage (V)
00000	[0.9 - 0.95[
00001	[0.95 - 1.0[
00010	[1.0 - 1.05[
...	...

## Conversion Management

The battery voltage monitor is turned on by setting the VBPEN and VBCEN bits in PCON (see Table 20). VBPEN bit is set first and VBCEN bit is set 1 ms later. An additional delay of 16 cycles is required before launching any conversion.

Launching a conversion is done by setting VBEN bit in VBAT (see Table 22). VBEN is automatically cleared at the end of the conversion which takes 34 clock periods. At this step two cases occur:

- Voltage is valid (inside conversion range)  
VBERR is cleared and conversion value is set in VB4:0 according to Table 18.
- Voltage is invalid (out of conversion range)  
VBERR is set and value reported by VB4:0 is indeterminate.

## Power Reduction Mode

Two power reduction modes are implemented in the AT85C51SND3B: the Idle mode and the Power-down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 mode as detailed in Section “X2 Feature”, page 31.

## Lock Mode

In order to allow firmware to efficiently enter in idle mode and not to lose any events that should come from one or more interrupts, power reduction modes entry are conditioned to an hardware bit: PMLCK in PCON.

PMLCK is set by software in each ISR that needs to report an event to the system and thus disables entry in power reduction mode and allows immediate processing of this event. It is cleared by software after exiting power reduction mode.

As shown in Figure 9, when power reduction modes are disabled by setting PMLCK, IDL and PD bits in PCON can not be set and idle or power down modes are not entered.

**Figure 9.** Power Reduction Controller Block Diagram

## Idle Mode

Idle mode is a power reduction mode that reduces the power consumption. In this mode, program execution halts. Idle mode freezes the clock to the CPU at known states while the peripherals continue to be clocked (refer to Section “System Clock Generator”, page 30). The CPU status before entering Idle mode is preserved, i.e., the program counter and program status word register retain their data for the duration of Idle mode. The contents of the SFRs and RAM are also retained.

### Entering Idle Mode

To enter Idle mode, the user must set the IDL bit in PCON register while PMLCK is cleared. The AT85C51SND3B enters Idle mode upon execution of the instruction that sets IDL bit. The instruction that sets IDL bit is the last instruction executed.

Note: If IDL bit and PD bit are set simultaneously, the AT85C51SND3B enter Power-down mode. Then it does not go in Idle mode when exiting Power-down mode.

### Exiting Idle Mode

There are 2 ways to exit Idle mode:

1. Generate an enabled interrupt.
  - Hardware clears IDL bit in PCON register which restores the clock to the CPU. Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Idle mode. The general-purpose flags (GF1 and GF0 in PCON register) may be used to indicate whether an interrupt occurred during normal operation or during Idle mode. When Idle mode is exited by an interrupt, the interrupt service routine may examine GF1 and GF0.
2. Generate a reset.
  - A logic high on the RST pin clears IDL bit in PCON register directly and asynchronously. This restores the clock to the CPU. Program execution momentarily resumes with the instruction immediately following the instruction that activated the Idle mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the AT85C51SND3B and vectors the CPU to address 0000h.

Note: During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated Idle mode should not write to a Port pin or to the external RAM.

## Power-down Mode

The Power-down mode places the AT85C51SND3B in a very low power state. Power-down mode stops the oscillator and freezes all clocks at known states (refer to the Section “Oscillator”, page 28). The CPU status prior to entering Power-down mode is preserved, i.e., the program counter, program status word register retain their data for the duration of Power-down mode. In addition, the SFRs and RAM contents are preserved.

### Entering Power-down Mode

To enter Power-down mode, set PD bit in PCON register while PMLCK is cleared. The AT85C51SND3B enters the Power-down mode upon execution of the instruction that sets PD bit. The instruction that sets PD bit is the last instruction executed.

### Exiting Power-down Mode

There are 2 ways to exit the Power-down mode:

1. Generate an enabled external interrupt.
  - The AT85C51SND3B provides capability to exit from Power-down using  $\overline{\text{INT0}}$ , INT1, and KIN3:0 inputs. In addition, using KIN input provides high or low level exit capability (see Section “Keyboard Interface”, page 240). Hardware clears PD bit in PCON register which starts the oscillator and restores

the clocks to the CPU and peripherals. Using  $\overline{\text{INTn}}$  input, execution resumes when the input is released (see Figure 10) while using KINx input, execution resumes after counting 1024 clock ensuring the oscillator is restarted properly (see Figure 11). This behavior is necessary for decoding the key while it is still pressed. In both cases, execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Power-down mode.

- Note:
1. The external interrupt used to exit Power-down mode must be configured as level sensitive (INT0 and INT1) and must be assigned the highest priority. In addition, the duration of the interrupt must be long enough to allow the oscillator to stabilize. The execution will only resume when the interrupt is de-asserted.
  2. Exit from power-down by external interrupt does not affect the SFRs nor the internal RAM content.

**Figure 10.** Power-down Exit Waveform Using  $\overline{\text{INT1:0}}$

**Figure 11.** Power-down Exit Waveform Using KIN3:0

- Note:
1. KIN3:0 can be high or low-level triggered.

2. Generate a reset.

- A logic high on the RST pin clears PD bit in PCON register directly and asynchronously. This starts the oscillator and restores the clock to the CPU and peripherals. Program execution momentarily resumes with the instruction immediately following the instruction that activated Power-down mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the AT85C51SND3B and vectors the CPU to address 0000h.

- Notes:
1. During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated the Power-down mode should not write to a Port pin or to the external RAM.
  2. Exit from power-down by reset redefines all the SFRs, but does not affect the internal RAM content.

## Reset

In order to secure the product functionality while in power-up or power-down phase or while in running phase, a number of internal mechanisms have been implemented. These mechanisms are listed below and detailed in the following paragraphs.

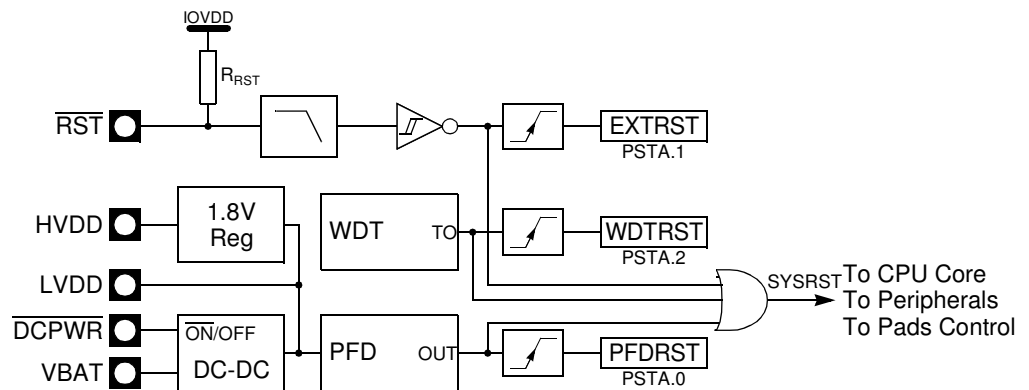

- External  $\overline{\text{RST}}$  input
- Power Fail Detector (brown-out)
- Watchdog timer
- Pads control

Figure 12 details the internal reset circuitry.

## Reset Source Reporting

In order for the firmware to take specific actions depending on the source which has currently reset the device, activated reset source is reported to the CPU by EXTRST, WDTRST, and PFDRST flags in PSTA register.

**Figure 12.** Internal Reset Circuitry

## Pads Level Control

As soon as one reset source is asserted, the pads go to their reset value. This ensures that pads level is steady during reset (e.g.  $\overline{\text{NFWP}}$  set to low level and then protecting Nand Flash against spurious writing).

The status of the Port pins during reset is detailed in Table 19.

**Table 19.** Pin State Under Reset Condition.

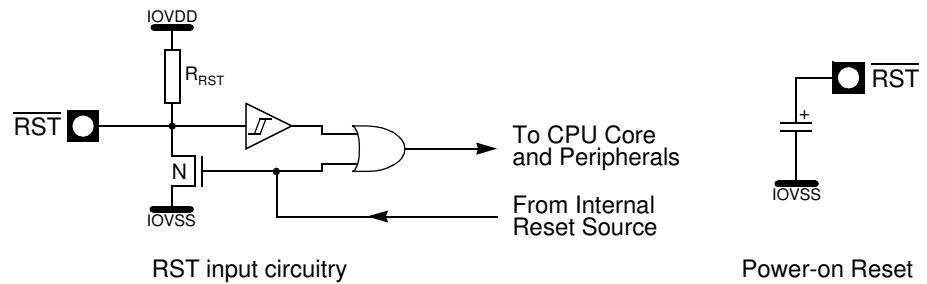

Port 0	Port 1	Port 2	Port 3	Port 4	Port 5	NFD7:0	$\overline{\text{NFWP}}$	$\overline{\text{NFCE0}}$
Float	H	H	H	H	H	Float	L	H

## External $\overline{\text{RST}}$ Input

In order to start-up (cold reset) or to restart (warm reset) properly the microcontroller, a low level has to be applied on the  $\overline{\text{RST}}$  pin. A bad level leads to a wrong initialization of the internal registers like SFRs, Program Counter... and to unpredictable behavior of the microcontroller. A proper device reset initializes the AT85C51SND3B and vectors the CPU to address 0000h.  $\overline{\text{RST}}$  input has a pull-up resistor allowing power-on reset by simply connecting an external capacitor to  $V_{\text{SS}}$  as shown in Figure 13. A warm reset can be applied either directly on the  $\overline{\text{RST}}$  pin or indirectly by an internal reset source such as the watchdog timer. Resistor value and input characteristics are discussed in the Section “DC Characteristics”, page 242.

**Figure 13.** Reset Circuitry and Power-On Reset

**Cold Reset**

2 conditions are required before enabling a CPU start-up:

- $V_{DD}$  must reach the specified  $V_{DD}$  range
- The level on X1 input pin must be outside the specification ( $V_{IH}$ ,  $V_{IL}$ )

If one of these 2 conditions are not met, the microcontroller does not start correctly and can execute an instruction fetch from anywhere in the program space. An active level applied on the RST pin must be asserted till both of the above conditions are met. A reset is active when the level  $V_{IL}$  is reached and when the pulse width covers the period of time where  $V_{DD}$  and the oscillator are not stabilized. 2 parameters have to be taken into account to determine the reset pulse width:

- $V_{DD}$  rise time,
- Oscillator startup time.

To determine the capacitor value to implement, the highest value of these 2 parameters has to be chosen.

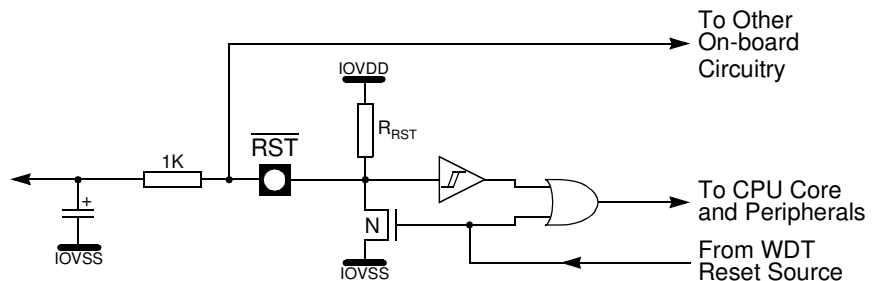

**Warm Reset**

To achieve a valid reset, the reset signal must be maintained for at least 2 machine cycles (24 oscillator clock periods) while the oscillator is running. The number of clock periods is mode independent (X2 or X1).

**Watchdog Timer Reset**

As detailed in Section “Watchdog Timer”, page 75, the WDT generates a 96-clock period pulse on the RST pin. In order to properly propagate this pulse to the rest of the application in case of external capacitor or power-supply supervisor circuit, a 1 k $\Omega$  resistor must be added as shown in Figure 14.

**Figure 14.** Reset Circuitry for WDT Reset-out Usage

**Power Fail Detector**

The Power Fail Detector (PFD) ensures that whole product is in reset when internal voltage is out of its limits specification. PFD limits are detailed in the Section “DC Characteristics”, page 242.

## Registers

**Table 20.** PCON Register

PCON (0.87h) – Power Control Register

7	6	5	4	3	2	1	0
VBCEN	VBPEN	DCPBST	GF0	DCEN	PMLCK	PD	IDL
Bit Number	Bit Mnemonic	Description					
7	VBCEN	<b>Battery Monitor Clock Enable Bit</b> Set to enable the clock of the battery monitoring. Clear to disable the clock of the battery monitoring.					
6	VBPEN	<b>Battery Monitor Power Enable Bit</b> Set to power the battery monitoring. Clear to unpower the battery monitoring.					
5	DCPBST	<b>DC-DC Converter Power Boost Bit</b> Set to disable DC-DC high power boost mode. Clear to enable DC-DC high power boost mode.					
4	GF0	<b>General-purpose flag 0</b> One use is to indicate whether an interrupt occurred during normal operation or during Idle mode.					
3	DCEN	<b>DC-DC Converter Enable Bit</b> Set to start the DC-DC converter or maintain its activity while $\overline{\text{DCPWR}}$ pin is asserted. Clear to stop the DC-DC converter and shut off the device if not powered by an external power supply.					
2	PMLCK	<b>Power Mode Lock Bit</b> Set to lock power-down or Idle mode entry by preventing PD or IDL bits from being set by software. Clear to unlock power-down or Idle mode entry.					
1	PD	<b>Power-down Mode bit</b> Cleared by hardware when an interrupt or reset occurs. Set to activate the Power-down mode when PMLCK is cleared. If IDL and PD are both set, PD takes precedence.					
0	IDL	<b>Idle Mode bit</b> Cleared by hardware when an interrupt or reset occurs. Set to activate the Idle mode when PMLCK is cleared. If IDL and PD are both set, PD takes precedence.					

Reset Value = 00011 0000b

5	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
4-0	VB4:0	<b>Battery Value</b> Refer to Table 18 for voltage value correspondence.					

Reset Value = 0000 0000b

## Clock Controller

The clock controller implemented in AT85C51SND3B derivatives is based on an on-chip oscillator feeding two on-chip Phase Lock Loop (PLL) dedicated for the USB controller (see Section “USB Controller”, page 85) and the Audio Controller (see Section “Audio Controller”, page 149). All internal clocks to the peripherals and CPU core are generated by this controller.

## Oscillator

X1 and X2 pins are the input and the output of a frequency power-optimized single-stage on-chip inverter (see Figure 15) that can be configured with off-chip components such as a Pierce oscillator (see Figure 16). Value of capacitors and crystal characteristics are detailed in the Section “DC Characteristics”, page 242.

## Authorized frequency

In order to be able to properly detect the oscillating frequency when in In System Programming mode and then generate the 480MHz requested for USB connection, only the following frequencies are authorized:  
12MHz, 13MHz, 16MHz, 19.2MHz, 19.5MHz, 20MHz, 24MHz and 26MHz.

## Power Optimization

In order to optimize the power consumption, oscillator gain can be adjusted by software depending on the crystal frequency. Such optimization is done after reset using OSCF1:0 bits in CKCON register (see Table 31) according to Table 23. Moreover if external frequency signal is input (X1 driven by a remote host) it is possible to switch off the internal amplifier by setting the OSCAMP bit in CKCON register as shown in Figure 15.

**Table 23.** Oscillator Frequency Configuration

OSCF1:0	Crystal Clock Frequency Range ( $F_{osc}$ )
00	22 - 26 MHz (default)
01	18 - 22 MHz
10	14 - 18 MHz.
11	10 - 14 MHz

The oscillator outputs a clock: the oscillator clock used to feed the clock generator and the system clock generator.

The oscillator clock can be disabled by entering the power-down reduction mode as detailed in the Section “Power Management”, page 19.

**Figure 15.** Oscillator Block Diagram and Symbol

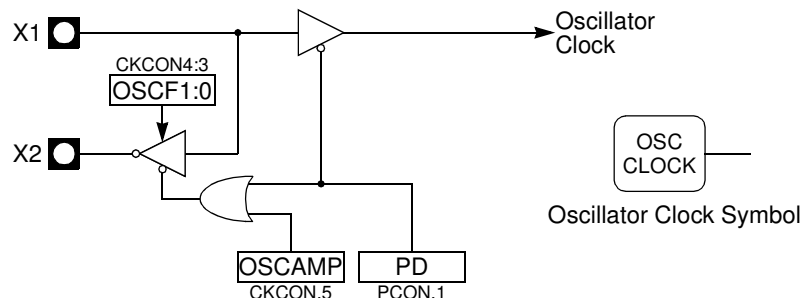

Figure 16. Crystal Connection

**Clock Generator**

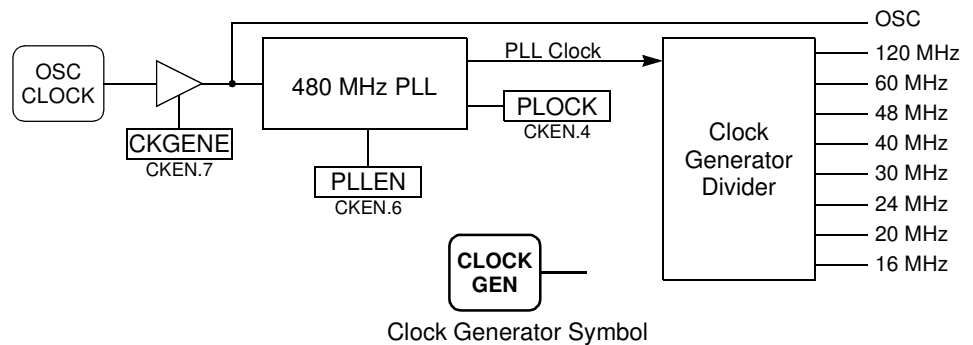

The clock generator provides the oscillator and higher frequency clocks to the System, the DFC, the memory controllers: Nand Flash and MMC controllers, the USB and the high speed Serial I/O port. It is based on a 480 MHz PLL namely the PLL clock followed by a frequency divider giving a broad range of available clock frequency: the CLOCK GEN clocks.

The clock generation is enabled by setting CKGENE bit in CKEN (see Table 32).

The PLL is enabled by setting PLEN bit in CKEN and reports a filtered lock status by the PLOCK Flag in CKEN.

As soon as the PLL is locked, the generated clocks can be used by the peripherals as detailed in the following sections.

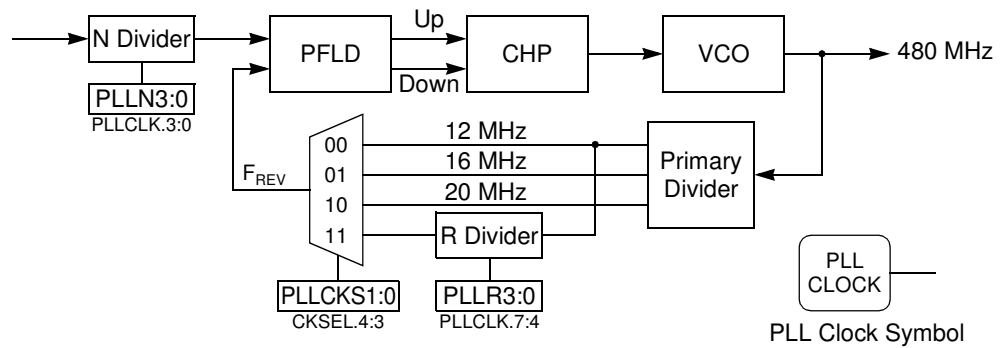

Figure 17. Clock Generator Block Diagram and Symbol

**480 MHz PLL**

The PLL is based on a Phase Frequency Comparator and Lock Detector block (PFLD) which makes the comparison between the reference clock coming from the 4-bit N divider (PLLN3:0 + 1 in PLLCLK) and the reverse clock coming from either fixed frequencies or the 4-bit R divider (PLLR3:0 + 1 in PLLCLK) and generates some pulses on the Up or Down signal depending on the edge position of the reverse clock. These pulses feed the Charge Pump block (CHP) that generates a voltage reference to the 480 MHz Voltage Controlled Oscillator (VCO) by injecting or extracting charges from an internal filter. The reverse clock selection mechanism is implemented in order to support many oscillator frequencies and to minimize the PLL output jitter.

**Figure 18.** PLL Block Diagram and Symbol

**Table 24.** PLL Reverse Clock Selection

PLLCKS1:0	Clock Selection ( $F_{REV}$ )
00	12 MHz (default)
01	16 MHz
10	20 MHz
11	12 MHz $\div$ (PLLR + 1)

*PLL Programming*

The PLL is programmed depending on the oscillator clock frequency. In order to minimize the output jitter,  $F_{REV}$  must be as higher as possible. Table 26 shows the PLL programming values and reverse frequency depending on some oscillator frequency.

**Table 25.** PLL Programming Values versus Input Frequency

$F_{osc}$ (MHz)	PLLCKS1:0	PLLN3:0 / N	PLLR3:0 / R	$F_{REV}$ (MHz)
12	00	0000	XXXX	12
13	11	1100 / 13	1011 / 12	1
16	01	0000	XXXX	16
19.2	11	0111 / 8	0100 / 5	2.4
19.5	11	1100 / 13	0111 / 8	1.5
20	10	0000	XXXX	20
24	00	0001 / 2	XXXX	12
26	11	1100 / 13	0101 / 6	2

**System Clock Generator**

In order to increase the system computation throughput, it is possible to switch the system clock to higher value when PLL is enabled. System clock generator block diagram is shown in Figure 19 and is based on a frequency selector controlled by SYSCKS1:0 bits in CKSEL (see Table 34) according to Table 26.

The CPU clock can be disabled by entering the idle reduction mode as detailed in the Section “Power Management”, page 19.

**Note:** In order to prevent any incorrect operation while dynamically switching the system frequency, user must be aware that all peripherals using the peripheral clock as time reference (timers, etc...) will have their time reference modified by this frequency change.

Figure 19. System Clock Generator Block Diagram and Symbols

Table 26. System Clock Selection

SYSCKS1:0	Clock Selection (F <sub>Sys</sub> )
00	F <sub>OSC</sub> (default)
01	24 MHz
10	30 MHz
11	40 MHz

**X2 Feature**

Unlike standard C51 products that require 12 clock periods per machine cycle, the AT85C51SND3B needs only 6 clock periods per machine cycle. This feature called the “X2 feature” can be enabled using the X2 bit<sup>(1)</sup> in CKCON and allows the AT85C51SND3B to operate in 6 or 12 clock periods per machine cycle. As shown in Figure 19, both CPU and peripheral clocks are affected by this feature. Figure 20 shows the X2 mode switching waveforms. After reset the standard mode is activated. In standard mode the CPU and peripheral clock frequency is the oscillator frequency divided by 2 while in X2 mode, it is the oscillator frequency.

Figure 20. Mode Switching Waveforms

**DFC/NFC Clock Generator**

In order to optimize the data transfer throughput between the DFC and the NFC, both peripherals share the same clock frequency. The DFC and NFC clock generator block diagram is shown in Figure 21 and is based on a frequency selector.

Frequency selection is done using DNFKS2:0 bits in CKSEL (see Table 33) according to Table 27.

Frequency is enabled by setting DNFKEN bit in CKEN.

**Figure 21.** DFC/NFC Clock Generator Block Diagram and Symbol

**Table 27.** DFC/NFC Clock Selection

DNFCKS2:0	Clock Selection ( $F_s$ )
000	$F_{OSC}$ (default)
001	60 MHz
010	48 MHz
011	40 MHz
100	30 MHz
101	24 MHz
110	20 MHz
111	16 MHz

### MMC Clock Generator

The MMC clock generator block diagram is shown in Figure 22 and is based on a frequency selector followed by a frequency divider.

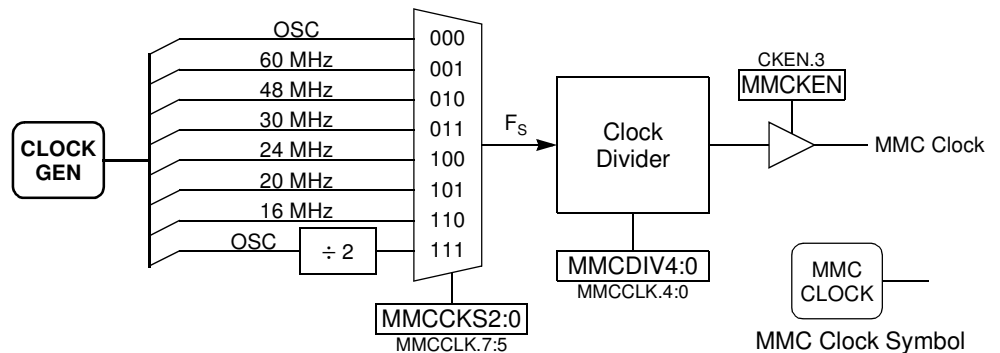

Frequency selection is done using MMCKS2:0 bits in MMCCLK (see Table 35) according to Table 28<sup>(1)</sup>.

Frequency division is done using MMCDIV4:0 bits in MMCCLK according to Table 29.

Frequency configuration (selection and division) must be done prior to enable the MMC clock generation by setting MMCKEN bit in CKEN.

Note: 1. To allow low frequency as low as 400 KHz (frequency needed in MMC identification phase),  $F_{OSC}$  selection can be divided by 2.

**Figure 22.** MMC Clock Generator Block Diagram and Symbol

**Table 28.** MMC Clock Selection

MMCKS2:0	Clock Selection ( $F_S$ )
000	$F_{OSC}$ (default)
001	60 MHz
010	48 MHz
011	30 MHz
100	24 MHz
101	20 MHz
110	16 MHz

**Table 29.** MMC Clock Divider

MMCDIV4:0	Clock Division
00000	Disabled (no clock out)
$\geq 00001$	$F_{MMC} = F_S \div MMCDIV$

**SIO Clock Generator**

As detailed in Figure 23, the SIO clock which feeds the internal SIO baud rate generator can be programmed using SIOCKS bit in CKSEL register according to Table 30 to generate either the oscillator frequency or a very high frequency allowing very high baud rate when PLL is enabled. SIO clock is enabled by SIOCKEN bit in CKEN register.

## Special Function Registers

### SFR Pagination

The AT85C51SND3B derivatives implement a SFR pagination mechanism which allows mapping of high number of peripherals in the SFR space. As shown in Figure 24, four pages are accessible through the PPCON (Peripheral Pagination Control) register (see Table 37). The four bits of PPCON: PPS0 to PPS3 are used to select one page as detailed in Table 36. Setting one bit of PPCON using the *setb* instruction automatically clears the 7 others: e.g. if page 0 is selected, selecting page 3 is done by the instruction *setb* PPS3 which clears PPS0.

By default, after reset selected page is page 0.

The PPCON content is automatically saved in a specific stack at each interrupt service routine entry during vectorization and restored at exit during *reti* execution.

**Figure 24.** SFR Pagination Block diagram

-	-	-	-	PPS3	PPS2	PPS1	PPS0

Bit Number	Bit Mnemonic	Description
7-4	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
3-0	PPS3:0	<b>Peripheral Page Select Bits</b> Refer to Table 36 for page decoding information.

Reset Value = 0000 0001b

## SFR Registers

The Special Function Registers (SFRs) of the AT85C51SND3B fall into the categories detailed in Table 39 to Table 58. Address is identified as “P.XXh” where P can take the values detailed in Table 38 and XXh is the hexadecimal address from 80h to FFh

**Table 38.** Page Address Notation

P	Comment
Y	Register mapped in all pages
3-0	Register mapped in the corresponding page

The SFRs mapping within pages is provided together with SFR reset value in Table 58 to Table 58. In these tables, the bit-addressable registers are identified by Note 1.

**Table 39.** C51 Core SFRs

Mnemonic	Add	Name	7	6	5	4	3	2	1	0
ACC	Y.E0h	Accumulator								
B	Y.F0h	B Register								
PSW	Y.D0h	Program Status Word	CY	AC	F0	RS1	RS0	OV	F1	P
SP	Y.81h	Stack Pointer								
DPL	Y.82h	Data Pointer Low Byte								
DPH	Y.83h	Data Pointer High Byte								
PPCON	Y.C0h	Peripheral Pagation	-	-	-	-	PPS3:0

  2. SVERS reset value depends on the silicon version 1111 1011 for AT85C51SND3B product.

## Memory Space

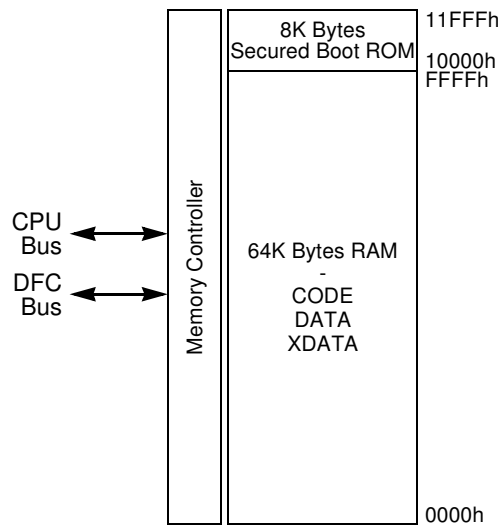

The AT85C51SND3B derivatives implement an “all in one” 64K bytes of RAM split between the three standard C51 memory segments:

- CODE
- DATA
- XDATA

To satisfy application needs in term of CODE and XDATA sizes, size and base address of XDATA and CODE segments and base address of DATA segment can be dynamically configured.

Figure 25 shows the memory space organization.

**Figure 25.** Memory Organization

## Memory Segments

### CODE Segment

The AT85C51SND3B executes up to 64K Bytes of program/code memory.

The AT85C51SND3B implements an additional 4K Bytes of on-chip boot ROM memory. This boot memory is delivered programmed with a boot strap software allowing loading of the application code from the Nand Flash Memory to the internal RAM. It also contains a boot loader software allowing In-System Programming (ISP).

### DATA Segment

The DATA segment is mapped in two separate segments:

- The lower 128 Bytes RAM segment
- The upper 128 Bytes RAM segment

#### *Lower 128 Bytes*

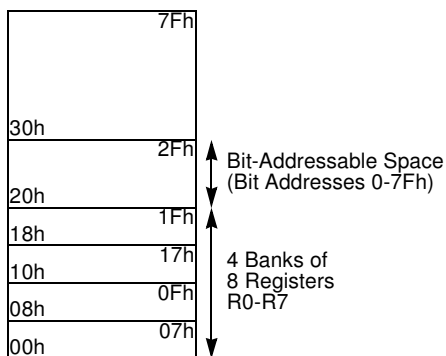

The lower 128 Bytes of RAM (see Figure 26) are accessible from address 00h to 7Fh using direct or indirect addressing modes. The lowest 32 Bytes are grouped into 4 banks of 8 registers (R0 to R7). 2 bits RS0 and RS1 in PSW register (see Table 64) select which bank is in use according to Table 63. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing, and can be used for context switching in interrupt service routines.

**Table 63.** Register Bank Selection

RS1	RS0	Description
0	0	Register bank 0 from 00h to 07h
0	1	Register bank 1 from 08h to 0Fh
1	0	Register bank 2 from 10h to 17h
1	1	Register bank 3 from 18h to 1Fh

The next 16 Bytes above the register banks form a block of bit-addressable memory space. The C51 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00h to 7Fh.

**Figure 26.** Lower 128 Bytes Internal RAM Organization

### Upper 128 Bytes

The upper 128 Bytes of RAM are accessible from address 80h to FFh using only indirect addressing mode. Using direct addressing mode within this address range selects the Special Function Registers, SFRs. For information on this segment, refer to the Section “Special Function Registers”, page 37.

### XDATA Segment

The on-chip expanded RAM (XRAM) are accessible using indirect addressing mode through MOVX instructions.

### Memory Configuration

As shown in Figure 25, the 64KB addressing space of the C51 is artificially increased by usage of logical address over a physical one. For example, the boot memory which contains the bootstrap software is implemented at physical address 10000h but is starting at logical address code 0000h which means that the bootstrap is first executed when a system reset occurs.

To achieve such logical mapping over the physical memory, some registers have been implemented to give the base address of the memory segments and their size:

- MEMCBAX (see Table 65) for the code segment base address.
- MEMDBAX (see Table 66) for the data segment base address.
- MEMXBAX (see Table 67) for the xdata segment base address.
- MEMCSX (see Table 68) for the code segment size.
- MEMXSX (see Table 69) for the code segment size.

The data segment is not programmable in size as it is a fixed 256-byte segment.

The Figure 27 shows the memory segments configuration after bootstrap execution along with an example of user memory segments configuration done during firmware start-up. In this figure italicized address are the logical address within segments.

**Figure 27.** Memory Segment Configuration

## Registers

**Table 64.** PSW Register

PSW (S:8Eh) – Program Status Word Register

	7	6	5	4	3	2	1	0

Reset Value MEMXSX = 0000 1110b

## Interrupt System

The AT85C51SND3B derivatives, like other control-oriented computer architectures, employ a program interrupt method. This operation branches to a subroutine and performs some service in response to the interrupt. When the subroutine completes, execution resumes at the point where the interrupt occurred. Interrupts may occur as a result of internal AT85C51SND3B activity (e.g., timer overflow) or at the initiation of electrical signals external to the microcontroller (e.g., keyboard). In all cases, interrupt operation is programmed by the system designer, who determines priority of interrupt service relative to normal code execution and other interrupt service routines. All of the interrupt sources are enabled or disabled by the system designer and may be manipulated dynamically.

A typical interrupt event chain occurs as follows:

- An internal or external device initiates an interrupt-request signal. The AT85C51SND3B latches this event into a flag buffer.
- The priority of the flag is compared to the priority of other interrupts by the interrupt handler. A high priority causes the handler to set an interrupt flag.
- This signals the instruction execution unit to execute a context switch. This context switch breaks the current flow of instruction sequences. The execution unit completes the current instruction prior to a save of the program counter (PC) and reloads the PC with the start address of a software service routine.
- The software service routine executes assigned tasks and as a final activity performs a RETI (return from interrupt) instruction. This instruction signals completion of the interrupt, resets the interrupt-in-progress priority and reloads the program counter. Program operation then continues from the original point of interruption.

Six interrupt registers are used to control the interrupt system:

- Two 8-bit registers are used to enable separately the interrupt sources: IEN0 and IEN1 registers (see Table 72 and Table 73).
- Four 8-bit registers are used to establish the priority level of the different sources: IPH0, IPL0, IPH1 and IPL1 registers (see Table 74 to Table 77).

## Interrupt System Priorities

Each interrupt sources of the AT85C51SND3B can be individually programmed to one of four priority levels. This is accomplished by one bit in the Interrupt Priority High registers (IPH0 and IPH1) and one bit in the Interrupt Priority Low registers (IPL0 and IPL1). This provides each interrupt source four possible priority levels according to Table 70.

**Table 70.** Priority Levels

IPHxx	IPLxx	Priority Level
0	0	0      Lowest
0	1	1
1	0	2
1	1	3      Highest

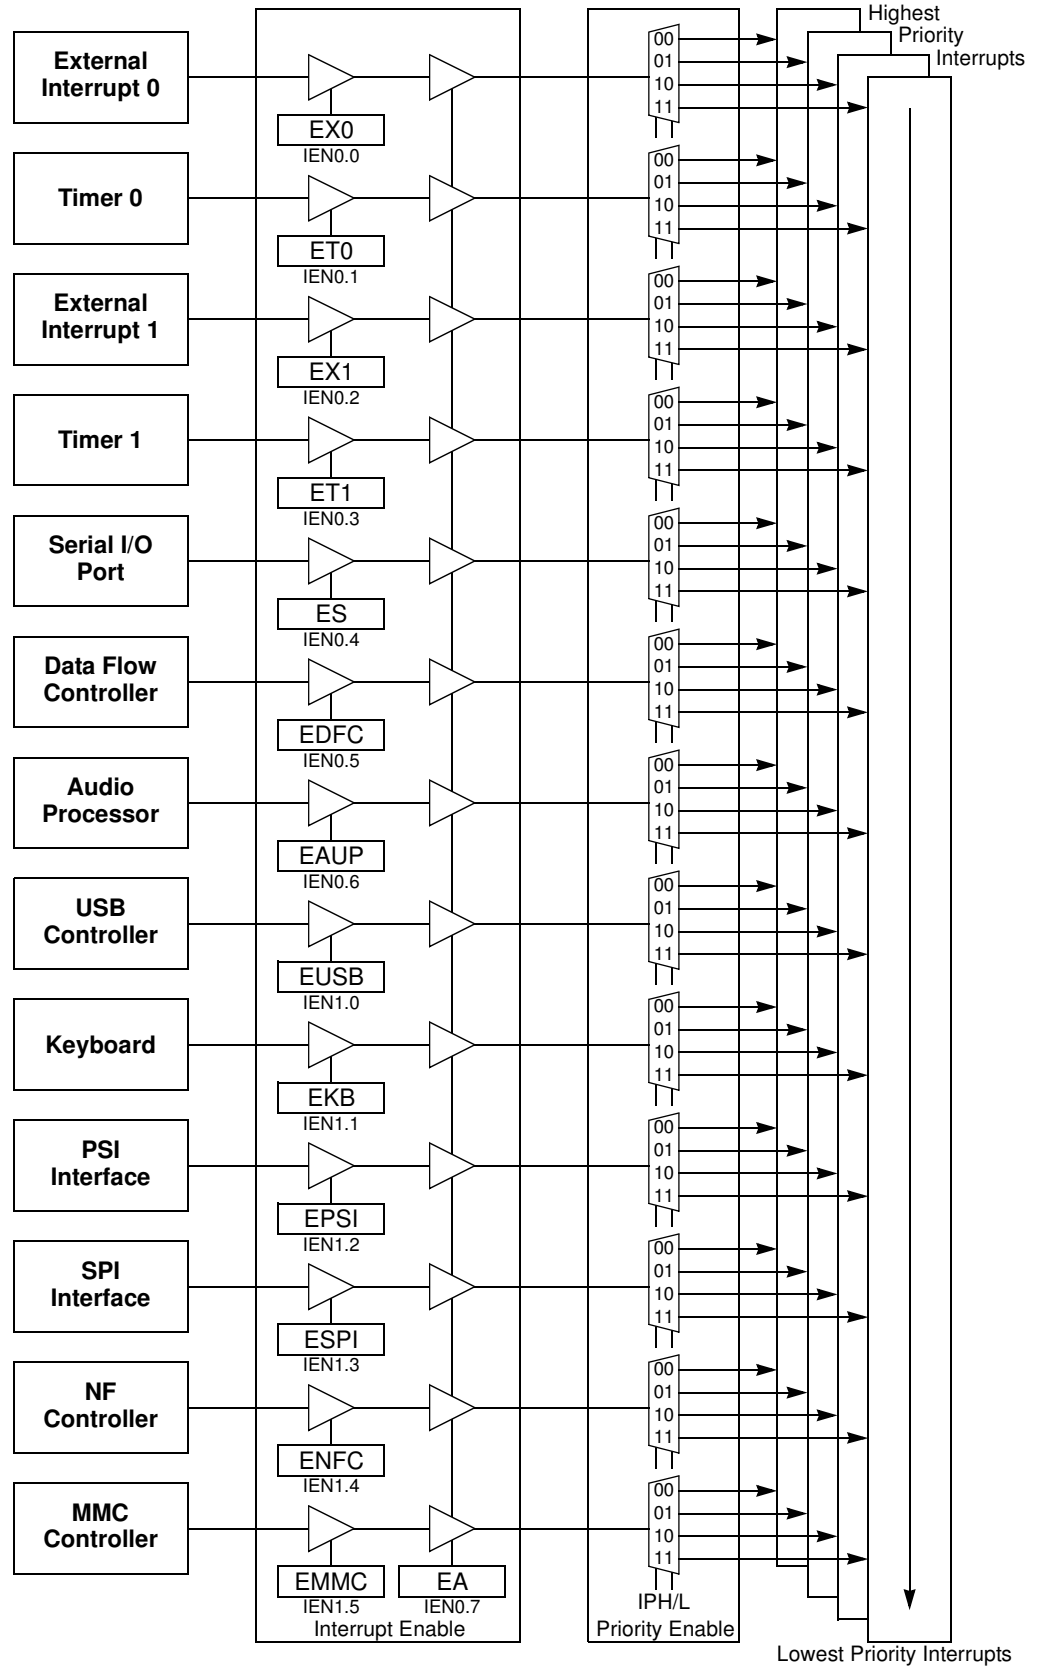

A low-priority interrupt is always interrupted by a higher priority interrupt but not by another interrupt of lower or equal priority. Higher priority interrupts are serviced before lower priority interrupts. The response to simultaneous occurrence of equal priority interrupts is determined by an internal hardware polling sequence detailed in Table 71. Thus, within each priority level there is a second priority structure determined by the polling sequence. The interrupt control system is shown in Interrupt Control System.

**Table 71.** Priority Within Same Level

Interrupt Name	Priority Number	Interrupt Address Vectors	Interrupt Request Flag Cleared by Hardware (H) or by Software (S)
$\overline{\text{INT0}}$	0 (Highest Priority)	C:0003h	H if edge, S if level
Timer 0	1	C:000Bh	H
$\overline{\text{INT1}}$	2	C:0013h	H if edge, S if level

Reserved	14 (Lowest Priority)	C:0073h	-

Figure 28. Interrupt Control System

## External Interrupts

### $\overline{\text{INT1:0}}$ Inputs

External interrupts  $\overline{\text{INT0}}$  and  $\overline{\text{INT1}}$  ( $\overline{\text{INTn}}$ ,  $n = 0$  or  $1$ ) pins may each be programmed to be level-triggered or edge-triggered, dependent upon bits  $\text{IT0}$  and  $\text{IT1}$  ( $\text{ITn}$ ,  $n = 0$  or  $1$ ) in  $\text{TCON}$  register as shown in  $\overline{\text{INT1:0}}$  Input Circuitry. If  $\text{ITn} = 0$ ,  $\overline{\text{INTn}}$  is triggered by a low level at the pin. If  $\text{ITn} = 1$ ,  $\overline{\text{INTn}}$  is negative-edge triggered. External interrupts are enabled with bits  $\text{EX0}$  and  $\text{EX1}$  ( $\text{EXn}$ ,  $n = 0$  or  $1$ ) in  $\text{IEN0}$ . Events on  $\overline{\text{INTn}}$  set the interrupt request flag  $\text{IEN}$  in  $\text{TCON}$  register. If the interrupt is edge-triggered, the request flag is cleared by hardware when vectoring to the interrupt service routine. If the interrupt is level-triggered, the interrupt service routine must clear the request flag and the interrupt must be de-asserted before the end of the interrupt service routine.

$\overline{\text{INT0}}$  and  $\overline{\text{INT1}}$  inputs provide both the capability to exit from Power-down mode on low level signals as detailed in Section “Exiting Power-down Mode”, page 22.

**Figure 29.**  $\overline{\text{INT1:0}}$  Input Circuitry

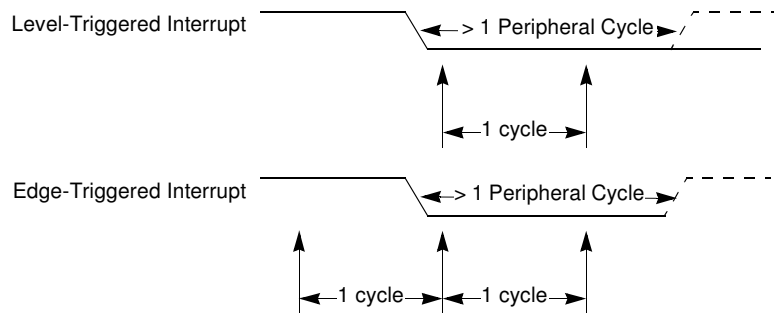

### $\text{KIN3:0}$ Inputs

External interrupts  $\text{KIN0}$  to  $\text{KIN3}$  provide the capability to connect a matrix keyboard. For detailed information on these inputs, refer to Section “Keyboard Interface”, page 240.

### Input Sampling

External interrupt pins ( $\overline{\text{INT1:0}}$  and  $\text{KIN3:0}$ ) are sampled once per peripheral cycle (6 peripheral clock periods) (see Minimum Pulse Timings). A level-triggered interrupt pin held low or high for more than 6 peripheral clock periods (12 oscillator in standard mode or 6 oscillator clock periods in X2 mode) guarantees detection. Edge-triggered external interrupts must hold the request pin low for at least 6 peripheral clock periods.

**Figure 30.** Minimum Pulse Timings

## Timers/Counters

The AT85C51SND3B derivatives implement 2 general-purpose, 16-bit Timers/Counters. They are identified as Timer 0 and Timer 1, and can be independently configured to operate in a variety of modes as a Timer or as an event Counter. When operating as a Timer, the Timer/Counter runs for a programmed length of time, then issues an interrupt request. When operating as a Counter, the Timer/Counter counts negative transitions on an external pin. After a preset number of counts, the Counter issues an interrupt request.

The various operating modes of each Timer/Counter are described in the following sections.

### Timer/Counter Operations

For instance, a basic operation is Timer registers THx and TLx ( $x = 0, 1$ ) connected in cascade to form a 16-bit Timer. Setting the run control bit (TRx) in TCON register (see Table 81) turns the Timer on by allowing the selected input to increment TLx. When TLx overflows it increments THx; when THx overflows it sets the Timer overflow flag (TFx) in TCON register. Setting the TRx does not clear the THx and TLx Timer registers. Timer registers can be accessed to obtain the current count or to enter preset values. They can be read at any time but TRx bit must be cleared to preset their values, otherwise, the behavior of the Timer/Counter is unpredictable.

The C/Tx# control bit selects Timer operation or Counter operation by selecting the divided-down peripheral clock or external pin Tx as the source for the counted signal. TRx bit must be cleared when changing the mode of operation, otherwise the behavior of the Timer/Counter is unpredictable.

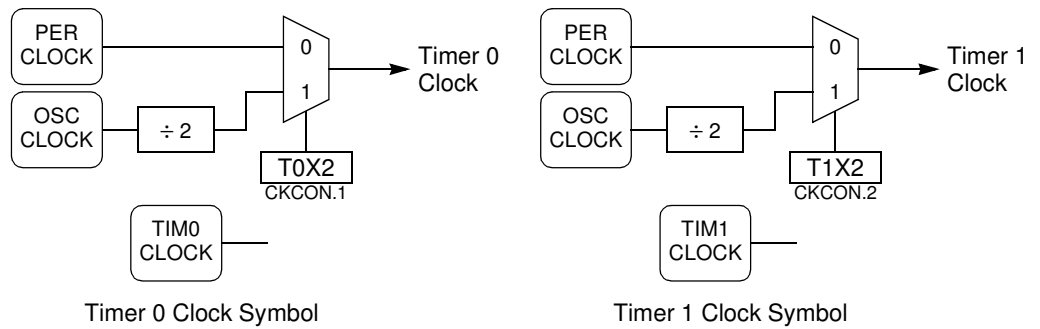

For Timer operation (C/Tx# = 0), the Timer register counts the divided-down peripheral clock. The Timer register is incremented once every peripheral cycle (6 peripheral clock periods). The Timer clock rate is  $F_{PER}/6$ , i.e.,  $F_{OSC}/12$  in standard mode or  $F_{OSC}/6$  in X2 mode.

For Counter operation (C/Tx# = 1), the Timer register counts the negative transitions on the Tx external input pin. The external input is sampled every peripheral cycles. When the sample is high in one cycle and low in the next one, the Counter is incremented. Since it takes 2 cycles (12 peripheral clock periods) to recognize a negative transition, the maximum count rate is  $F_{PER}/12$ , i.e.,  $F_{OSC}/24$  in standard mode or  $F_{OSC}/12$  in X2 mode. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full peripheral cycle.

### Timer Clock Controller

As shown in Figure 31, the Timer 0 (FT0) and Timer 1 (FT1) clocks are derived from either the peripheral clock ( $F_{PER}$ ) or the oscillator clock ( $F_{OSC}$ ) depending on the T0X2 and T1X2 bits in CKCON register. These clocks are issued from the Clock Controller block as detailed in Section "Oscillator", page 28. When T0X2 or T1X2 bit is set, the Timer 0 or Timer 1 clock frequency is fixed and equal to the oscillator clock frequency divided by 2. When cleared, the Timer clock frequency is equal to the oscillator clock frequency divided by 2 in standard mode or to the oscillator clock frequency in X2 mode.

**Figure 31.** Timer 0 and Timer 1 Clock Controller and Symbols

## Timer 0

Timer 0 functions as either a Timer or event Counter in four modes of operation. Figure 32, Figure 34, Figure 36, and Figure 38 show the logical configuration of each mode.

Timer 0 is controlled by the four lower bits of TMOD register (see Table 82) and bits 0, 1, 4 and 5 of TCON register (see Table 81). TMOD register selects the method of Timer gating (GATE0), Timer or Counter operation (C/T0#) and mode of operation (M10 and M00) according to Table 78. TCON register provides Timer 0 control functions: overflow flag (TF0), run control bit (TR0), interrupt flag (IE0) and interrupt type control bit (IT0).

For normal Timer operation (GATE0 = 0), setting TR0 allows TL0 to be incremented by the selected input. Setting GATE0 and TR0 allows external pin INT0 to control Timer operation.

Timer 0 overflow (count rolls over from all 1s to all 0s) sets TF0 flag generating an interrupt request.

It is important to stop Timer/Counter before changing mode.

**Table 78.** Timer/counter 0 Operating Modes

M10	M00	Mode	Operation
0	0	0	8-bit Timer/Counter (TH0) with 5-bit prescaler (TL0).
0	1	1	16-bit Timer/Counter.
1	0	2	8-bit auto-reload Timer/Counter (TL0).
1	1	3	TL0 is an 8-bit Timer/Counter. TH0 is an 8-bit Timer using Timer 1's TR0 and TF0 bits.

### Mode 0 (13-bit Timer)

Mode 0 configures Timer 0 as a 13-bit Timer which is set up as an 8-bit Timer (TH0 register) with a modulo 32 prescaler implemented with the lower five bits of TL0 register (see Figure 32). The upper three bits of TL0 register are indeterminate and should be ignored. Prescaler overflow increments TH0 register. Figure 33 gives the overflow period calculation formula.

**Figure 32.** Timer/Counter x (x = 0 or 1) in Mode 0

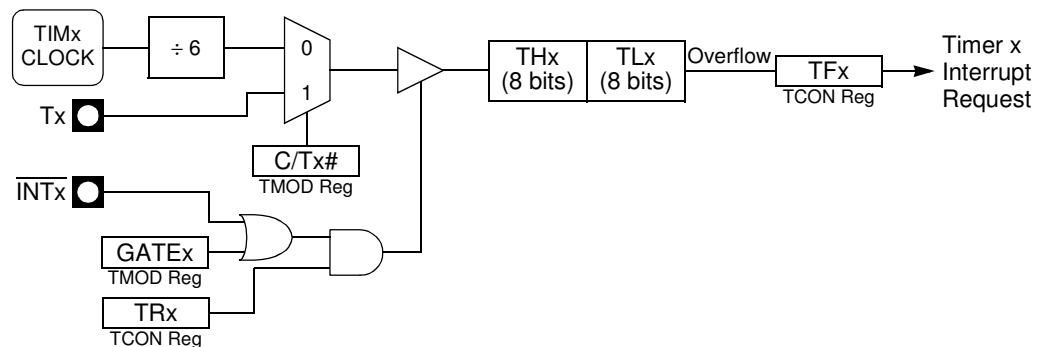

**Figure 33.** Mode 0 Overflow Period Formula

$$TFx_{PER} = \frac{6 \cdot (16384 - (THx, TLx))}{F_{TIMx}}$$

**Mode 1 (16-bit Timer)**

Mode 1 configures Timer 0 as a 16-bit Timer with TH0 and TL0 registers connected in cascade (see Figure 34). The selected input increments TL0 register. Figure 35 gives the overflow period calculation formula when in timer mode.

**Figure 34.** Timer/Counter x (x = 0 or 1) in Mode 1

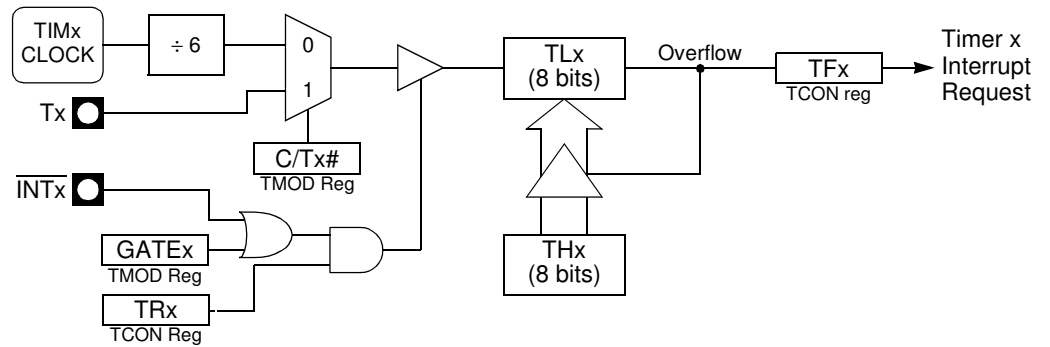

**Figure 35.** Mode 1 Overflow Period Formula

$$TFx_{PER} = \frac{6 \cdot (65536 - (THx, TLx))}{F_{TIMx}}$$

**Mode 2 (8-bit Timer with Auto-Reload)**

Mode 2 configures Timer 0 as an 8-bit Timer (TL0 register) that automatically reloads from TH0 register (see Figure 36). TL0 overflow sets TF0 flag in TCON register and reloads TL0 with the contents of TH0, which is preset by software. When the interrupt request is serviced, hardware clears TF0. The reload leaves TH0 unchanged. The next reload value may be changed at any time by writing it to TH0 register. Figure 37 gives the auto-reload period calculation formula when in timer mode.

**Figure 36.** Timer/Counter x (x = 0 or 1) in Mode 2

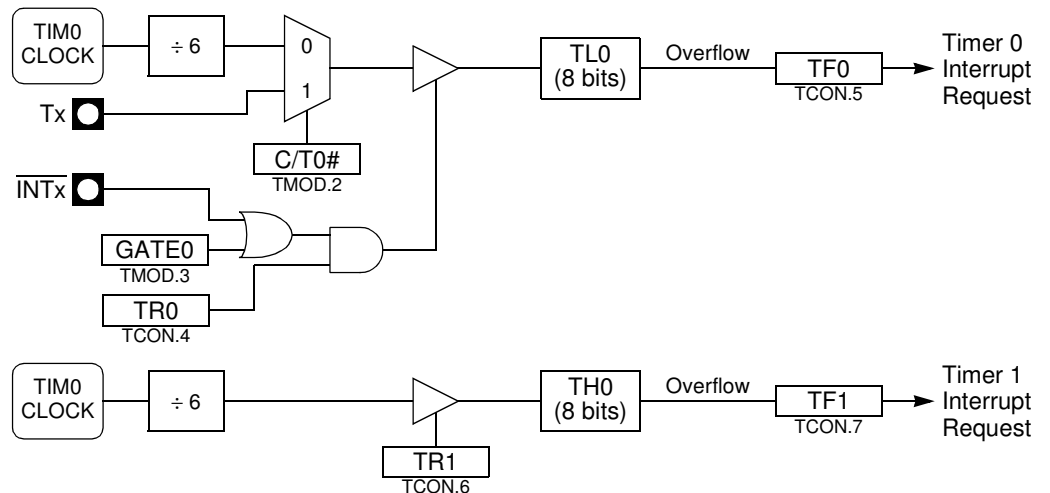

**Figure 37.** Mode 2 Auto-reload Period Formula

$$TF_{xPER} = \frac{6 \cdot (256 - THx)}{F_{TIMx}}$$

### Mode 3 (2 x 8-bit Timers)

Mode 3 configures Timer 0 such that registers TL0 and TH0 operate as separate 8-bit Timers (see Figure 38). This mode is provided for applications requiring an additional 8-bit Timer or Counter. TL0 uses the Timer 0 control bits C/T0# and GATE0 in TMOD register, and TR0 and TF0 in TCON register in the normal manner. TH0 is locked into a Timer function (counting  $F_{TF1}/6$ ) and takes over use of the Timer 1 interrupt (TF1) and run control (TR1) bits. Thus, operation of Timer 1 is restricted when Timer 0 is in mode 3. Figure 39 gives the auto-reload period calculation formulas for both TF0 and TF1 flags.

**Figure 38.** Timer/Counter 0 in Mode 3: 2 8-bit Counters

**Figure 39.** Mode 3 Overflow Period Formula

$$TF0_{PER} = \frac{6 \cdot (256 - TL0)}{F_{TIM0}}$$

$$TF1_{PER} = \frac{6 \cdot (256 - TH0)}{F_{TIM0}}$$

## Timer 0 Enhanced Mode

Timer 0 overflow period can be increased in all modes by enabling a divider as detailed in Figure 40. This mode is implemented to allow higher time periods as it can be used for example as a scheduler time base with auto-reload (mode 2). Timer 0 enhanced mode is enabled by programming T0ETB2:0 bits in SCHCLK (see Table 87) to a value other than 000b and according to Table 79.

**Figure 40.** Timer/Counter 0 Enhanced Mode

**Table 79.** Timer/counter 0 Enhanced Overflow Period

T0ETB2	T0ETB1	T0ETB0	New TF0 Overflow Period
0	0	0	TF0 <sub>PER</sub> ÷ 1 (divider disable)
0	0	1	TF0 <sub>PER</sub> ÷ 2
0	1	0	TF0 <sub>PER</sub> ÷ 4
0	1	1	TF0 <sub>PER</sub> ÷ 8
1	0	0	TF0 <sub>PER</sub> ÷ 16
1	0	1	TF0 <sub>PER</sub> ÷ 32
1	1	0	TF0 <sub>PER</sub> ÷ 64
1	1	1	TF0 <sub>PER</sub> ÷ 128

## Timer 1

Timer 1 is identical to Timer 0 except for Mode 3 which is a hold-count mode and for the enhanced mode which is not available. The following comments help to understand the differences:

- Timer 1 functions as either a Timer or event Counter in three modes of operation. Figure 32, Figure 34, and Figure 36 show the logical configuration for modes 0, 1, and 2. Timer 1's mode 3 is a hold-count mode.
- Timer 1 is controlled by the four high-order bits of TMOD register (see Table 82) and bits 2, 3, 6 and 7 of TCON register (see Table 81). TMOD register selects the method of Timer gating (GATE1), Timer or Counter operation (C/T1#) and mode of operation (M11 and M01) according to Table 80. TCON register provides Timer 1 control functions: overflow flag (TF1), run control bit (TR1), interrupt flag (IE1) and interrupt type control bit (IT1).
- Timer 1 can serve as the Baud Rate Generator for the Serial Port. Mode 2 is best suited for this purpose.
- For normal Timer operation (GATE1 = 0), setting TR1 allows TL1 to be incremented by the selected input. Setting GATE1 and TR1 allows external pin INT1 to control Timer operation.
- Timer 1 overflow (count rolls over from all 1s to all 0s) sets the TF1 flag generating an interrupt request.
- When Timer 0 is in mode 3, it uses Timer 1's overflow flag (TF1) and run control bit (TR1). For this situation, use Timer 1 only for applications that do not require an interrupt (such as a Baud Rate Generator for the Serial Port) and switch Timer 1 in and out of mode 3 to turn it off and on.

- It is important to stop the Timer/Counter before changing modes.

**Table 80.** Timer/counter 1 Operating Modes

M11	M01	Mode	Operation
0	0	0	8-bit Timer/Counter (TH1) with 5-bit prescaler (TL1).
0	1	1	16-bit Timer/Counter.
1	0	2	8-bit auto-reload Timer/Counter (TL1).
1	1	3	Timer/Counter halted. Retains count.

**Mode 0 (13-bit Timer)**

Mode 0 configures Timer 1 as a 13-bit Timer, which is set up as an 8-bit Timer (TH1 register) with a modulo-32 prescaler implemented with the lower 5 bits of the TL1 register (see Figure 32). The upper 3 bits of TL1 register are ignored. Prescaler overflow increments TH1 register.

**Mode 1 (16-bit Timer)**

Mode 1 configures Timer 1 as a 16-bit Timer with TH1 and TL1 registers connected in cascade (see Figure 34). The selected input increments TL1 register.

**Mode 2 (8-bit Timer with Auto-Reload)**

Mode 2 configures Timer 1 as an 8-bit Timer (TL1 register) with automatic reload from TH1 register on overflow (see Figure 36). TL1 overflow sets TF1 flag in TCON register and reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

**Mode 3 (Halt)**

Placing Timer 1 in mode 3 causes it to halt and hold its count. This can be used to halt Timer 1 when TR1 run control bit is not available i.e. when Timer 0 is in mode 3.

**Interrupt**

Each Timer handles one interrupt source that is the timer overflow flag TF0 or TF1. This flag is set every time an overflow occurs. Flags are cleared when vectoring to the Timer interrupt routine. Interrupts are enabled by setting ETx bit in IEN0 register. This assumes interrupts are globally enabled by setting EA bit in IEN0 register.

## Watchdog Timer

The AT85C51SND3B derivatives implement a hardware Watchdog Timer (WDT) that automatically resets the chip if it is allowed to time out. The WDT provides a means of recovering from routines that do not complete successfully due to software or hardware malfunctions.

## Description

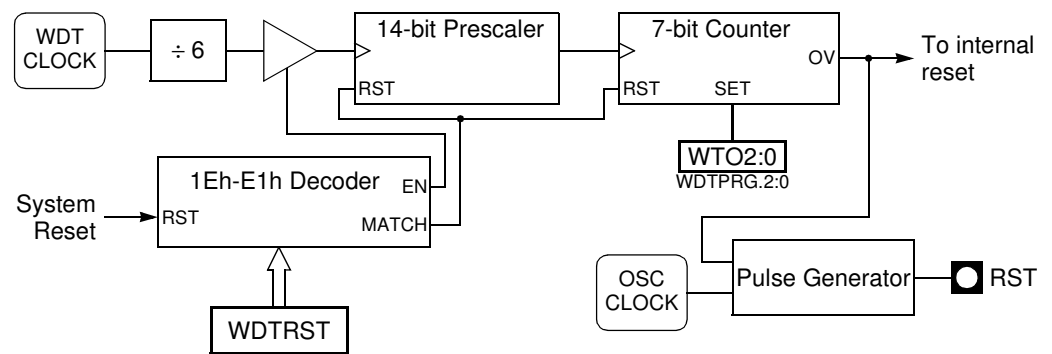

The WDT consists of a 14-bit prescaler followed by a 7-bit programmable counter. As shown in Figure 42, the 14-bit prescaler is fed by the WDT clock detailed in Section “Clock Controller”.

The Watchdog Timer Reset register (WDTRST, see Table 89) provides control access to the WDT, while the Watchdog Timer Program register (WDTPRG, see Figure 90) provides time-out period programming.

Three operations control the WDT:

- Chip reset clears and disables the WDT.
- Programming the time-out value to the WDTPRG register.
- Writing a specific 2-Byte 1Eh-E1h sequence to the WDTRST register clears and enables the WDT.

**Figure 42.** WDT Block Diagram

## Clock Controller

As shown in Figure 43 the WDT clock ( $F_{WDT}$ ) is derived from either the peripheral clock ( $F_{PER}$ ) or the oscillator clock ( $F_{OSC}$ ) depending on the WTX2 bit in CKCON register. These clocks are issued from the Clock Controller block as detailed in Section “Oscillator”, page 28. When WTX2 bit is set, the WDT clock frequency is fixed and equal to the oscillator clock frequency divided by 2. When cleared, the WDT clock frequency is equal to the oscillator clock frequency divided by 2 in standard mode or to the oscillator clock frequency in X2 mode.

**Figure 43.** WDT Clock Controller and Symbol

## Operation

After reset, the WDT is disabled. The WDT is enabled by writing the sequence 1Eh and E1h into the WDTRST register. As soon as it is enabled, there is no way except the chip reset to disable it. If it is not cleared using the previous sequence, the WDT overflows and forces a chip reset. This overflow generates a low level 96 oscillator periods pulse on the RST pin to globally reset the application (refer to Section “Watchdog Timer Reset”, page 25).

The WDT time-out period can be adjusted using WTO2:0 bits located in the WDTPRG register accordingly to the formula shown in Figure 44. In this formula, WTOval represents the decimal value of WTO2:0 bits. Table 88 reports the time-out period depending on the WDT frequency.

**Figure 44.** WDT Time-Out Formula

$$WDT_{TO} = \frac{6 \cdot (2^{14} \cdot 2^{WTOval})}{F_{WDT}}$$

**Table 88.** WDT Time-Out Computation

WTO2	WTO1	WTO0	WDT <sub>TO</sub> (ms) / F <sub>WDT</sub>						
			6 MHz <sup>(1)</sup>	8 MHz <sup>(1)</sup>	10 MHz <sup>(1)</sup>	12 MHz	16 MHz <sup>(2)</sup>	20 MHz <sup>(2)</sup>	24 MHz <sup>(2)</sup>
0	0	0	16.38	12.28	9.83	8.19	6.14	4.92	4.1
0	0	1	32.77	24.57	19.66	16.38	12.28	9.83	8.19
0	1	0	65.54	49.14	39.32	32.77	24.57	19.66	16.36
0	1	1	131.07	98.28	78.64	65.54	49.14	39.32	32.77
1	0	0	262.14	196.56	157.29	131.07	98.28	78.64	65.54
1	0	1	524.29	393.1	314.57	262.14	196.56	157.29	131.07
1	1	0	1049	786.24	629.15	524.29	393.12	314.57	262.14
1	1	1	2097	1572	1258	1049	786.24	629.15	524.29

- Notes:
1. These frequencies are achieved in X1 mode or in X2 mode when WTX2 = 1:  
F<sub>WDT</sub> = F<sub>OSC</sub> ÷ 2.
  2. These frequencies are achieved in X2 mode when WTX2 = 0: F<sub>WDT</sub> = F<sub>OSC</sub>.

## Behavior during Idle and Power-down Modes

Operation of the WDT during power reduction modes deserves special attention.

The WDT continues to count while the CPU core is in Idle mode. This means that you must dedicate some internal or external hardware to service the WDT during Idle mode. One approach is to use a peripheral Timer to generate an interrupt request when the Timer overflows. The interrupt service routine then clears the WDT, reloads the peripheral Timer for the next service period and puts the CPU core back into Idle mode.

The Power-down mode stops all phase clocks. This causes the WDT to stop counting and to hold its count. The WDT resumes counting from where it left off if the Power-down mode is terminated by INTO, INT1 or keyboard interrupt. To ensure that the WDT does not overflow shortly after exiting the Power-down mode, it is recommended to clear the WDT just before entering Power-down mode.

The WDT is cleared and disabled if the Power-down mode is terminated by a reset.

## Data Flow Controller

The Data Flow Controller (DFC) implemented in the AT85C51SND3B derivatives is the multimedia data transfer manager. Up to two data transfers can be established through two physical data channels between a source peripheral and a destination peripheral. Figure 45 shows which peripherals are connected to the internal bus which are: the CPU internal bus, the multimedia data bus and the DFC control bus.

**Figure 45.** DFC Internal Architecture

### CPU Interface

The DFC interfaces to the C51 core through the following special function registers: DFCON the DFC control register, DFCSTA the channel status register, DFCCON the channel control register, DFD0 and DFD1, the physical channel 0 and channel 1 data flow descriptor registers and DFCRC the CRC data register.

### Clock Unit

The DFC clock is generated based on the clock generator as detailed in Section “DFC/NFC Clock Generator”, page 31. Depending on the power mode (USB powered or battery powered) and the throughput desired, different clock values may be selected to control the data transfer. The DFC does not receive its system clock until DFEN bit in DFCON is set, i.e. DFC enabled.

### Data Flow Descriptor

As shown in Table 91 the data flow is characterized by a 5-byte data flow descriptor: the DFD composed of 4 fields. The data flow descriptor is written byte by byte to DFD0 (channel 0) or to DFD1 (channel 1). As soon as a DFD has been fully written, the channel is enabled and data flow transfer starts when both source and destination are ready to send and receive data respectively.

Table 92 shows the different peripherals (source or destination) ID number. These numbers are used to program the SID and the DID in the DFD.

**Table 91.** Data Flow Descriptor Content

Byte Number	Byte Mnemonic	Description
0	SID	<b>Source Identifier</b> See Table 92 for peripheral ID number.
1	DID	<b>Destination Identifier</b> See Table 92 for peripheral ID number.
2	DPS	<b>Data Packet Size</b> Decimal value giving the packet size as $2^{DPS}$ . DPS takes value from 0 (1-byte packet size) to 13 (8192-byte packet size). Packet size is limited to 8192 bytes in case of DPS value greater than 13
3	DFSH	<b>Data Flow Size</b> 16-bit wide data leading to data flow size from 1 to $2^{16} - 1$ data packets. Writing 0x0000 to this field enables continuous data flow.
4	DFSL	

**Table 92.** Peripheral ID Number

ID Number	Peripheral
0	C51 RAM
1	USB Controller
2	Audio Controller 1
3	Audio Controller 2
4	PSI Controller
5	SPI Controller
6	SIO Controller
7	Nand Flash Controller
8	MMC/SD Controller
$9 \leq n \leq 14$	Reserved
15	Null Device

## CRC Processor

In order to verify integrity of data transferred through the DFC, a CRC calculation can be enabled using DFCRCEN bit in DFCON. It consists in a 16-bit CRC which is the remainder after transfer data (MSB first) is divided by G(X). Polynomial formula is:  $G(X) = X^{16} + X^{15} + X^2 + 1$ .

CRC16 operates on channel 0 only.

After an hardware reset, the CRC value is 0x0000 but can be set to any initial value by writing two bytes<sup>(1)</sup> (MSB first) in the DFCRC register.

At the end of the data flow transfer<sup>(2)</sup>, CRC is available to user by reading two bytes<sup>(1)</sup> (MSB first) from the DFCRC register.

- Notes:
1. This double write or read sequence can be reset by clearing the CRCEN bit.
  2. The CRC value is not reset at start-up of a new data transfer.

## Null Device

The null device is used to allow CRC calculation on some data transfer (see Section “CRC Processor”). When selected as destination, the null device is always ready and simply acknowledges and discards data coming from the source. When

selected as source, the null device is always ready and sends the data (2 bytes) of the initialized CRC value MSB first.

## Channel Priority

The Data Flow Controller bandwidth is shared between Channel 0 and Channel 1. In case both channels are ready to transfer data, bus bandwidth is shared on a byte by byte basis.

In order to allocate maximum bandwidth to a specified channel, priority can be assigned to channel 0 or to channel 1 by setting the DFPRIO1:0 bits in DFCON according to Table 93.

DFPRIO1:0 can be modified at any time while transfer is on-going or not.

**Table 93.** Channel Priority Assignment

DFPRIO1	DFPRIO0	Assignment Description
0	0	No priority assigned: channel 0 & channel 1 have same priority.
0	1	Priority assigned to channel 0.
1	0	Priority assigned to channel 1.
1	1	Reserved, do not set both bits.

## Data Flow Status

An on-going data flow transfer is reported to user using the bits DFBSY0 and DFBSY1 in DFCSTA. These bits are set as soon as the DFD has been fully written to the corresponding channel and cleared at the end of transfer or abort.

Source peripheral and destination peripheral status is dynamically reported by SRDY0, DRDY0, SRDY1, DRDY1 ready flags in DFCSTA.

## Data Flow Abort

The DFC allows asynchronous abort of any on-going flow. Abort is controlled by the DFABT0, DFABT1, the Channel Data Flow Abort control bits in DFCCON and DFABTM the Data Flow Abort Mode control bit in DFCON.

Setting DFABT0 or DFABT1 while a flow transfer is on-going triggers on the corresponding channel an immediate or delayed abort depending on the DFABTM value. DFABTM cleared triggers an immediate abort where data flow transfer is stopped at the end of the on-going byte transfer while DFABTM set triggers a delayed abort where data flow transfer is stopped at the end of the on-going data packet transfer. Above abort modes set the End of Flow interrupt flag of the corresponding channel.

Setting DFABT0 or DFABT1 while a DFD is under writing will reset the DFD content of the corresponding channel. Such abort does not set the End of Flow interrupt flag of the corresponding channel.

## Abort Status

In case a data flow transfer is aborted, the remaining number of data packets to be transmitted can be retrieved by reading two bytes with MSB first from the data flow descriptor register DFD0 (channel 0) or to DFD1 (channel 1). This feature is of interest in case of logical data flow management over a physical channel.

Note: In case of immediate abort, returned value is not significant since part of the DP is already transmitted.

**Figure 46.** Immediate Data Flow Abort Diagram

**Figure 47.** Delayed Data Flow Abort Diagram

**Data Flow Configuration**

Prior to any operation, the DFC must be configured in term of clock source and channel priority, then DFC can be enabled. Each time a data flow must be established, a data flow descriptor must be written to the DFC.

**Interrupts**

As shown in Figure 48, the DFC interrupt request is generated by 2 different sources: the EOFI0 flag or EOFI1 flag in DFCSTA. Both sources can be enabled separately by using the EOFE0 and EOFE1 bits in DFCCON. A global enable of the DFC interrupt is provided by setting the EDFC bit in IENx register. The interrupt is requested each time one of the 2 sources is asserted.

EOFI0 or EOFI1 flags are set:

- at the end of a data flow on respective channel.
- after an immediate abort command at the end of the byte transfer.
- after a delayed abort at the end of the data packet transfer.

Note: An abort command never sets flags while in the process of writing DFD.

EOFI0 and EOFI1 flags must be cleared by software by setting EOFIA0 and EOFIA1 bits in DFCCON, in order to acknowledge the interrupt. Setting these flags by software has no effect.

**Figure 48.** DFC Interrupt System

## Registers

**Table 94.** DFCON Register

DFCON (1.89h) – DFC Control Register

7	6	5	4	3	2	1	0
-	DFRES	-	DFCRCEN	DFPRIO1	DFPRIO0	DFABTM	DFEN
Bit Number	Bit Mnemonic	Description					
5	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
6	DFRES	<b>Data Flow Controller Reset Bit</b> Set then clear this bit to reset the Data Flow Controller by software.					
5	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
4	DFCRCEN	<b>CRC Enable Bit</b> Set to enable CRC calculation on channel 0. Clear to disable CRC calculation.					
3-2	DFPRIO1:0	<b>Data Flow Channel Priority Assignment Bits</b> Refer to Table 93 for channel priority assignment description.					
1	DFABTM	<b>Data Flow Abort Mode Bit</b> Set to trigger a delayed abort. Clear to trigger an immediate abort.					
0	DFEN	<b>Data Flow Controller Enable Bit</b> Set to enable the Data Flow Controller. Clear to disable the Data Flow Controller.					

Reset Value = 0000 0000b

7-0	CRCD7:0	<b>CRC 2-byte Data FIFO</b> First reading of DFCRC returns the MSB of the CRC16 data while second reading returns the LSB. First writing to DFCRC writes the MSB of the initial value of the CRC16 data while second writing writes the LSB.					

Reset Value = 0000 0000b

## USB Controller

The AT85C51SND3B derivatives implement a USB controller allowing the AT85C51SND3B to act as a USB device or a USB host.

The main features of the USB controller:

- Full-speed and high-speed device.
- Full-speed host with OTG compliance.
- Automatic Data Flow Controller (DFC) transfer without CPU support.
- 2368 bytes of DPRAM.
- Up to 7 endpoints/pipes
  - 1 endpoint of 64 bytes (default control),
  - 2 endpoints of 512 bytes max, (one or two banks),
  - 4 endpoints of 64 bytes max, (one or two banks).

## Description

The C51 core interfaces with the USB Controller using a set of special function registers detailed in Table 49, page 40.

As shown in Figure 49, the USB controller is based on seven functional blocks:

- the PLL clock (see Section “Clock Generator”, page 29) which delivers 480 MHz clock for USB high-speed mode support.
- the USB HS/FS pad supporting speed negotiation, attach/detach and data transfer
- the USB OTG pad supporting OTG negotiation
- the device controller allowing AT85C51SND3B to act as a device
- the host controller allowing AT85C51SND3B to act as a device
- the 2368-byte dual port RAM for endpoints and pipes memory
- the interrupt controller

**Figure 49.** USB Controller Block Diagram

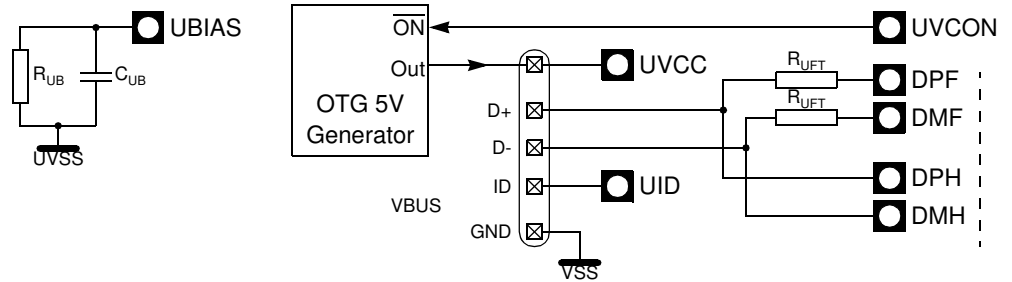

## USB Connection

Figure 50 shows the connection of the AT85C51SND3B to the USB connector and the connection of the RC filter to the UBIAS pin. DPF and DMF pins are connected through 2 termination resistors.

Value of all discrete components is detailed in the Section “DC Characteristics”, page 242.

**Figure 50. USB Connection**

## General Operating Modes

### Introduction

After a hardware reset, the USB controller is disabled.

When enabled, the USB controller has to run the Device Controller or the Host Controller. This is performed using the ID detection.

- If the ID pin is not connected to ground, the ID bit is set by hardware (internal pull up on the UID pad) and the USB Device controller is selected.
- The ID bit is cleared by hardware when a low level has been detected on the ID pin. The Device controller is then disabled and the Host controller enabled.

The software anyway has to select the mode (Host, Device) in order to access to the Device controller registers or to the Host controller registers, which are multiplexed. For example, even if the USB controller has detected a Device mode (pin ID high), the software shall select the device mode (bit HOST cleared), otherwise it will access to the host registers. This is also true for the Host mode.

### Power-On and Reset

Figure 51 shows the USB controller main states after power-on.

**Figure 51. USB Controller Reset State Machine**

USB Controller state after an hardware reset is 'Reset'. In this state:

- USBE is not set,
- the macro clock is stopped in order to minimize the power consumption ( $FRZCLK=1$ ),
- the macro is disabled,
- the pad is in the suspend mode,
- the Host and Device USB controllers internal states are reset.

- The DPACC bit and the DPADD10:0 field can be set by software. The DPRAM is not cleared.
- The SPDCONF bits can be set by software.

After setting USBE, the USB Controller enters in the Host or in the Device state (according to the UID pin level). The selected controller is 'Idle'.

The USB Controller can at any time be 'stopped' by clearing USBE. In fact, clearing USBE acts as an hardware reset.

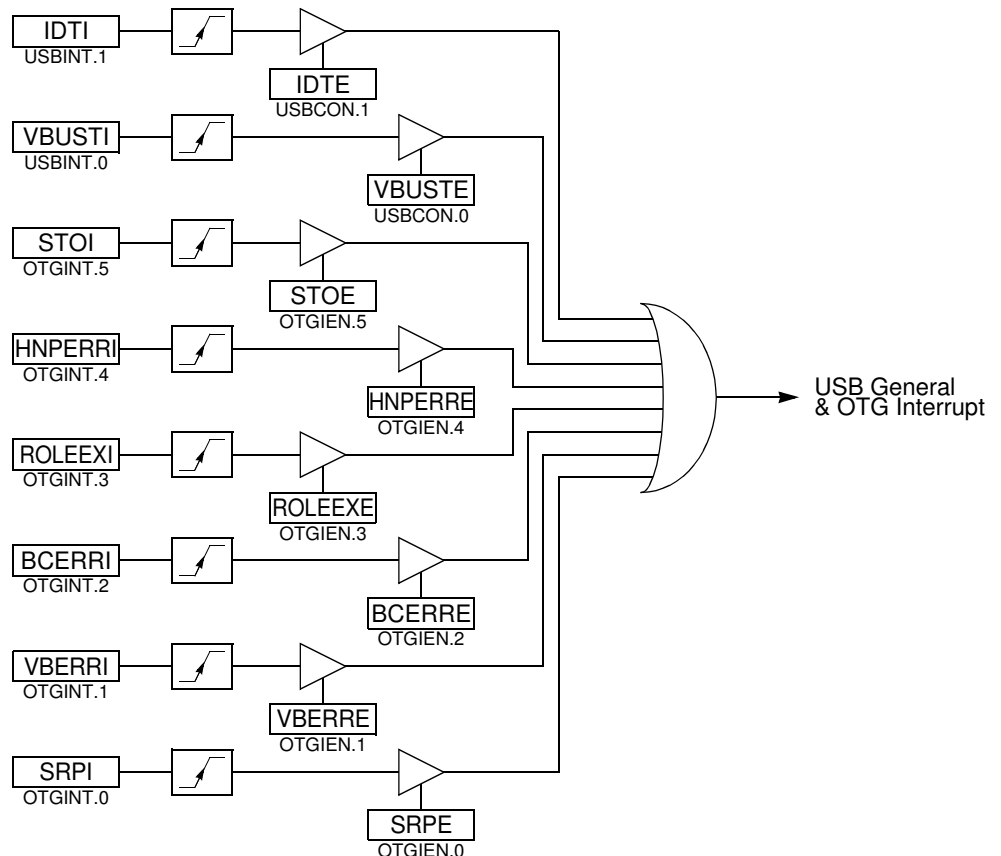

## Interrupts

As shown in Figure 52, the USB controller implements five main global interrupt sources: the USB general and OTG interrupts detailed in Figure 53, the USB device and endpoint interrupts detailed in Section "Interrupts", page 113, and the USB host and pipe interrupts detailed in Section "Interrupt", page 134.

**Figure 52.** USB Interrupt System

**Figure 53.** USB General and OTG Interrupt System

There are 2 kinds of interrupts: processing (i.e. their generation are part of the normal processing) and exception (errors).

Processing interrupts are generated when the following events are triggered:

- IDTI: ID Pad detection (insert, remove)
- VBUSTI: VBUS plug-in detection (insert, remove)
- SRPI: SRP detected
- ROLEEXI: Role Exchanged

Exception Interrupts are generated when the following events are triggered:

- VBERRI: Drop on VBUS Detected
- BCERRI: Error during the B-Connection
- HNPERRI: HNP Error
- STOI: Time-out detected during Suspend mode

## Power modes

### Idle Mode

In this mode, the CPU core is halted (CPU clock stopped). The Idle mode is taken regardless of the USB controller state (running or not). The CPU wakes up on any USB interrupts.

### Power Down

In this mode, the oscillator and PLL are stopped and the CPU and peripherals are frozen. The CPU “wakes up” when:

- the WAKEUPI interrupt is triggered in the Peripheral mode (HOST cleared),
- the RXRSMI or the SRPI interrupt is triggered in the Host mode (HOST set).
- the IDTI interrupt is triggered
- the VBUSTI interrupt is triggered

### Freeze Clock

The firmware has the ability to reduce the power consumption by setting the FRZCLK bit, which freezes the clock of USB controller. When FRZCLK is set, it is still possible to have an access to the following registers:

- USBCON, USBSTA, USBINT
- DPRAM direct access (DPADD10:0, UxDATX)
- UDCON (detach, ...)
- UDINT
- UDIEN
- UHCON
- UHINT
- UHIEN

Moreover, when FRZCLK is set, only the following interrupts may be triggered:

- WAKEUPI
- IDTI
- VBUSTI

## Speed Control

### Device Mode

When the USB interface is configured in device mode, the speed selection (Full Speed or High Speed) is performed automatically by the USB controller during the USB Reset. At the end of the USB reset, the USB controller automatically enables or disables high-speed terminations and pull-up.

Note: It is possible to force the speed of the protocol, through the SPDCONF1:0 bits. For normal operations, SPDCONF1:0 must be cleared.

For all other operations (e.g. running in Full-Speed only), SPDCONF1:0 shall be written before enabling the controller (USB\_E set), in order to avoid any side effects. The following table summarizes all the possible configurations:

**Table 100.** Speed configuration

Mode	SPDCONF1:0	Description
Peripheral	00	<b>Normal Mode (default)</b> Use High-Speed pad in Full-Speed or High-Speed.
	01	<b>Full-Speed only mode (Full-Speed pad)</b> Shall be done before setting USB_E.
	10	<b>High-Speed only mode (High-Speed pad)</b> Shall be used in debug mode.
	11	<b>Full-Speed only mode (High-Speed pad)</b>
Host	XX	<b>Use Full-Speed pad</b>

Clearing USB\_E resets SPDCONF1:0.

### Host Mode

When the USB interface is configured in host mode, internal pull down resistors are activated on both DMF and DPF lines.

### Memory Access Capability

The CPU has the capability to directly access to the USB internal memory (DPRAM). The memory access mode is performed using UDPADDH and UDPADDL registers.

To enter in this mode:

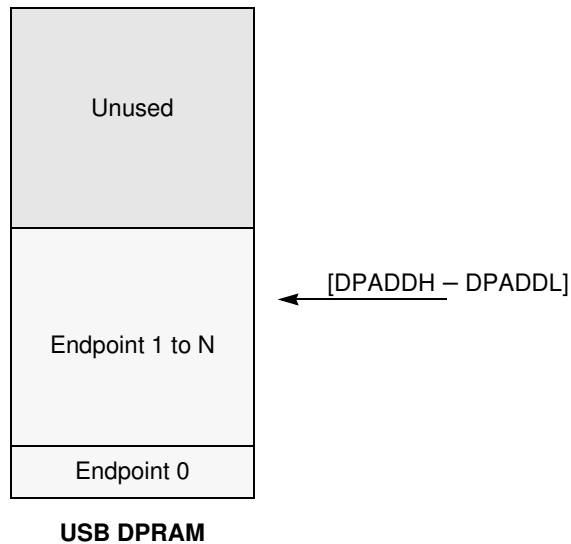

- USB\_E bit must be cleared.
- DPACC bit and the base address DPADD10:0 must be set.

The DPACC bit and DPADD10:0 field can be used by the firmware even if the USB\_E bit is cleared.

Then, a read or a write in UEDATX (device mode) or in UPDATX (host mode) is performed according to DPADD10:0 and the base address DPADD10:0 field is automatically increased. The endpoint FIFO pointers and the value of the UxNUM registers are discarded in this mode.

The aim of this functionality is to use the DPRAM as extra-memory.

When using this mode, there is no influence over the USB controller.

## Memory Management

The controller only supports the following memory allocation management:

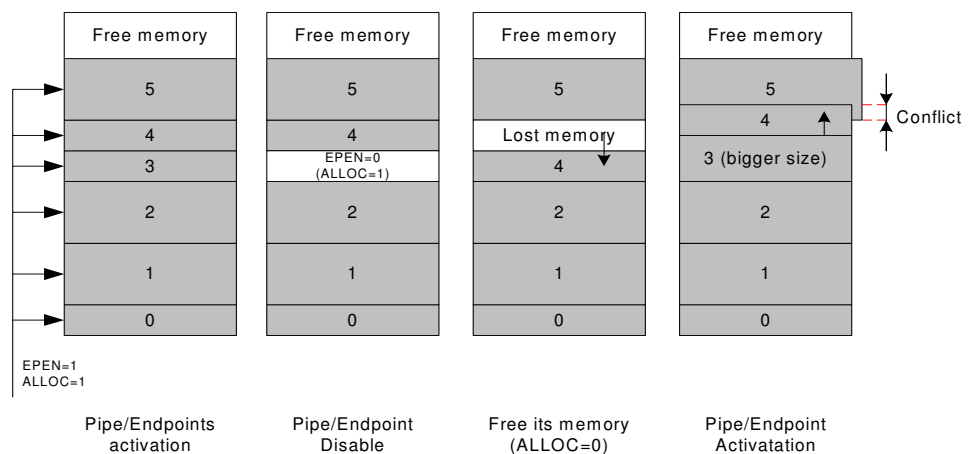

The reservation of a Pipe or an Endpoint can only be made in the growing order (Pipe/Endpoint 0 to the last Pipe/Endpoint). The firmware shall thus configure them in the same order.

The reservation of a Pipe or an Endpoint “ $k^i$ ” is done when its ALLOC bit is set. Then, the hardware allocates the memory and insert it between the Pipe/Endpoints “ $k^{i-1}$ ” and “ $k^{i+1}$ ”. The “ $k^{i+1}$ ” Pipe/Endpoint memory “slides” up and its data is lost. Note that the “ $k^{i+2}$ ” and upper Pipe/Endpoint memory does not slide.

Clearing a Pipe enable (PEN) or an Endpoint enable (EPEN) does not clear neither its ALLOC bit, nor its configuration (EPSIZE/PSIZE, EPBK/PBK). To free its memory, the firmware should clear ALLOC. Then, the “ $k^{i+1}$ ” Pipe/Endpoint memory automatically “slides” down. Note that the “ $k^{i+2}$ ” and upper Pipe/Endpoint memory does not slide.

The following figure illustrates the allocation and reorganization of the USB memory in a typical example:

**Figure 54.** Allocation and reorganization USB memory flow

- First, Pipe/Endpoint 0 to Pipe/Endpoint 5 are configured, in the growing order. The memory of each is reserved in the DPRAM.
- Then, the Pipe/Endpoint 3 is disabled (EPEN=0), but its memory reservation is internally kept by the controller.
- Its ALLOC bit is cleared: the Pipe/Endpoint 4 “slides” down, but the Pipe/Endpoint 5 does not “slide”.
- Finally, if the firmware chooses to reconfigure the Pipe/Endpoint 3, with a bigger size. The controller reserved the memory after the endpoint 2 memory and automatically “slide” the Pipe/Endpoint 4. The Pipe/Endpoint 5 does not move and a memory conflict appear, in that both Pipe/Endpoint 4 and 5 use a common area. The data of those endpoints are potentially lost.

- Notes:
1. the data of Pipe/Endpoint 0 are never lost whatever the activation or deactivation of the higher Pipe/Endpoint. Its data is lost if it is deactivated.
  2. Deactivate and reactivate the same Pipe/Endpoint with the same parameters does not lead to a “slide” of the higher endpoints. For those endpoints, the data are preserved.
  3. CFGOK is set by hardware even in the case that there is a “conflict” in the memory allocation.

## PAD suspend

Figure 55 and Figure 56 illustrate the pad behaviour:

- In the “idle” mode, the pad is put in low power consumption mode.
- In the “active” mode, the pad is working.

**Figure 55.** Pad Behaviour State Machine

The SUSPI flag indicates that a suspend state has been detected on the USB bus. This flag automatically puts the USB pad in Idle state. The detection of a non-idle event sets the WAKEUPI flag and wakes-up the USB pad.

**Figure 56.** Pad Behavior Waveforms

Moreover, the pad can also be put in the “idle” mode if the DETACH bit is set. It come back in the active mode when the DETACH bit is cleared.

## OTG Timers Customizing

It is possible to refine some OTG timers thanks to the OTGTCON register (see Table 108). This register is multiplexed with the OTGCON register. The timers are as defined in the OTG specification:

- AWaitVrise time-out. [OTG] chapter 6.6.5.1
- VbBusPulsing. [OTG] chapter 5.3.4
- PdTmOutCnt. [OTG] chapter 5.3.2
- SRPDetTmOut. [OTG] chapter 5.3.3

**Table 101.** OTG Timer Configuration

PAGE1:0	VALUE2:0	Timing Parameter
00	00	AWaitVrise time-out = 20 ms.
	01	AWaitVrise time-out = 50 ms.
	10	AWaitVrise time-out = 70 ms.
	11	AWaitVrise time-out = 100 ms.
01	00	VbBusPulsing = 15 ms.
	01	VbBusPulsing = 23 ms.
	10	VbBusPulsing = 31 ms.
	11	VbBusPulsing = 40 ms.
10	00	PdTmOutCnt = 96 ms.
	01	PdTmOutCnt = 105 ms.
	10	PdTmOutCnt = 118 ms.
	11	PdTmOutCnt = 131 ms.
11	00	SRPDetTmOut = 10 $\mu$ s.
	01	SRPDetTmOut = 100 $\mu$ s.
	10	SRPDetTmOut = 1 ms.
	11	SRPDetTmOut = 11 ms.

## Plug-in detection

The USB connection is detected by the VBUS pad, thanks to the following architecture:

**Figure 57.** Plug-in Detection Input Block Diagram

The control logic of the UVCC pad outputs 2 signals:

- The “session\_valid” signal is active high when the voltage on the UVCC pin is higher or equal to 1.4V.
- The “Va\_Vbus\_valid” signal is active high when the voltage on the UVCC pin is higher or equal to 4.4V.

In the Host mode, the VBUS flag follows the next hysteresis rule:

- VBUS is set when the voltage on the UVCC pin is higher or equal to 4.4 V.
- VBUS is cleared when the voltage on the UVCC pin is lower than 1.4 V.

In the Peripheral mode, the VBUS flag follows the next rule:

- VBUS is set when the voltage on the UVCC pin is higher or equal to 1.4 V.
- VBUS is cleared when the voltage on the UVCC pin is lower than 1.4 V.

The VBUSTI interrupt is triggered at each transition of the VBUS flag.

## ID Detection

The ID pin transition is detected thanks to the following architecture:

**Figure 58.** ID Detection Input Block Diagram

By default, (no A-plug or B-plug), the macro is in the Peripheral mode (internal pull-up). The IDTI interrupt is triggered when a A-plug (Host) is plugged or unplugged. The interrupt is not triggered when a B-plug (Peripheral) is plugged or unplugged.

The IDTI interrupt may be triggered even if the USB controller is disabled.

## Registers

### USB general registers

**Table 102.** USBCON Register

USBCON (1.E1h) – USB General Control Register

7	6	5	4	3	2	1	0
USBE	HOST	FRZCLK	OTGPADE	-	-	IDTE	VBUSTE
Bit Number	Bit Mnemonic	Description					
7	USBE	<b>USB Controller Enable Bit</b> Set to enable the USB controller. Clear to disable and reset the USB controller, to disable the USB transceiver and to disable the USB controller clock inputs.					
6	HOST	<b>HOST Bit</b> Set to access to the Host registers. Clear to access to the Device registers.					
5	FRZCLK	<b>Freeze USB Clock Bit</b> Set to disable the clock inputs (the “Resume Detection” is still active) and save power consumption. Clear to enable the clock inputs.					
4	OTGPADE	<b>OTG Pad Enable</b> Set to enable the OTG pad. Clear to disable the OTG pad. Note that this bit can be set/cleared even if USBE= 0 (this allows the VBUS detection even if the USB macro is disable).					
3-2	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
1	IDTE	<b>ID Transition Interrupt Enable Bit</b> Set this bit to enable the ID Transition interrupt generation. Clear this bit to disable the ID Transition interrupt generation.					

Bit Number	Bit Mnemonic	Description
0	VBUSTE	<b>VBUS Transition Interrupt Enable Bit</b> Set this bit to enable the VBUS Transition interrupt generation. Clear this bit to disable the VBUS Transition interrupt generation.

Reset Value = 0010 0000b

5	STOI	<b>Suspend Time-out Error Interrupt Flag</b> Set by hardware when a time-out error (more than 150 ms) has been detected after a suspend. Shall be cleared by software. See for more details.					
4	HNPERRI	<b>HNP Error Interrupt Flag</b> Set by hardware when an error has been detected during the protocol. Shall be cleared by software. See for more details.					

Bit Number	Bit Mnemonic	Description
3	ROLEEXI	<b>Role Exchange Interrupt Flag</b> Set by hardware when the USB controller has successfully swapped its mode, due to an HNP negotiation: Host to Device or Device to Host. Shall be cleared by software. See for more details.
2	BCERRI	<b>B-Connection Error Interrupt Flag</b> Set by hardware when an error occur during the B-Connection. Shall be cleared by software.
1	VBERRI	<b>V-Bus Error Interrupt Flag</b> Set by hardware when a drop on VBus has been detected. Shall be cleared by software.
0	SRPI	<b>SRP Interrupt Flag</b> Set by hardware when a SRP has been detected. Shall be used in the Host mode only. Shall be cleared by software.

Reset Value = 0000 0000b

## USB Software Operating modes

Depending on the USB operating mode, the software should perform some of the following operations:

### Power On the USB interface

- Power-On USB pads regulator
- Wait USB pads regulator ready state
- Configure PLL interface
- Enable PLL
- Check PLL lock
- Enable USB interface
- Configure USB interface (USB speed, Endpoints configuration...)
- Wait for USB VBUS information connection
- Attach USB device

### Power Off the USB interface

- Detach USB interface
- Disable USB interface
- Disable PLL
- Disable USB pin regulator

### Suspending the USB interface

- Clear Suspend Bit
- Set USB suspend clock
- Disable PLL
- Be sure to have interrupts enable to exit sleep mode
- Make the MCU enter sleep mode

### Resuming the USB interface

- Enable PLL
- Wait PLL lock
- Clear USB suspend clock
- Clear Resume information

## USB Device Operating modes

### Introduction

The USB device controller supports high speed and full speed data transfers. In addition to the default control endpoint, it provides six other endpoints, which can be configured in control, bulk, interrupt or isochronous modes:

- Endpoint 0:  
programmable size FIFO up to 64 bytes, default control endpoint.
- Endpoints 1 and 2:  
programmable size FIFO up to 512 bytes in ping-pong mode.
- Endpoints 3 to 6:  
programmable size FIFO up to 64 bytes in ping-pong mode.

The controller starts in the “idle” mode. In this mode, the pad consumption is reduced to the minimum.

### Power-On and Reset

Figure 59 shows the USB device controller main states after power-on.

**Figure 59.** USB Device Controller Reset State Machine

The reset state of the Device controller is:

- the macro clock is stopped in order to minimize the power consumption (FRZCLK set)
- the USB device controller internal state is reset (all the registers are reset to their default value. Note that DETACH is set.)
- the endpoint banks are reset
- the D+ or D- pull up are not activated (mode Detach)

The D+ or D- pull-up will be activated as soon as the DETACH bit is cleared and VBUS is present.

The macro is in the ‘Idle’ state after reset with a minimum power consumption and does not need to have the PLL activated to enter in this state.

The USB device controller can at any time be reset by clearing USBE.

### Speed Identification

The high-speed reset is managed by the hardware. At the connection, the host makes a reset that can be:

- a classic reset (Full-speed) or
- a High-speed reset (High-speed).

At the end of the reset process (Full or High), the end of reset interrupt (EORSTI) is generated. Then the CPU should read the SPEED bit to know the speed mode of the device.

Note that the USB device controller starts in the Full-speed mode after power on.

## Endpoint Reset

An endpoint can be reset at any time by setting in the UERST register the bit corresponding to the endpoint (EPRST<sub>x</sub>). This resets:

- the internal state machine on that endpoint,
- the Rx and Tx banks are cleared and their internal pointers are restored,
- the UEINTX, UESTA0X and UESTA1X are restored to their reset value.

The data toggle field remains unchanged.

The other registers remain unchanged.

The endpoint configuration remains active and the endpoint is still enabled.

The endpoint reset may be associated with a clear of the data toggle command (RSTDT bit) as an answer to the CLEAR\_FEATURE USB command.

## USB Reset

When an USB reset is detected on the USB line, the next operations are performed by the controller:

- all the endpoints are disabled, except the default control endpoint,
- the default control endpoint is reset (see Section “Endpoint Reset” for more details).
- The data toggle of the default control endpoint is cleared.

## Endpoint Selection

Prior to any operation performed by the CPU, the endpoint must first be selected. This is done by:

- Clearing EPNUMS.
- Setting EPNUM with the endpoint number which will be managed by the CPU.

The CPU can then access to the various endpoint registers and data.

In the same manner, if the endpoint must be accessed by the DFC, it must first be selected. This is done by:

- Setting EPNUMS.
- Setting EPNUM with the endpoint number which will be managed by the DFC.
- Setting DFCDY when the data-flow is ready to take place.

The DFC can then access to the banks (read / write).

The controller internally keeps in memory the EPNUM for the CPU and the EPNUM for the DFC. In fact, there are 2 EPNUM registers multiplexed by the EPNUMS bit. Each of them can be read or written by the CPU.

These two registers permits to easily switch from an endpoint under DFC data transfer to the default control endpoint when a SETUP is received, without reprogramming the EPNUM register:

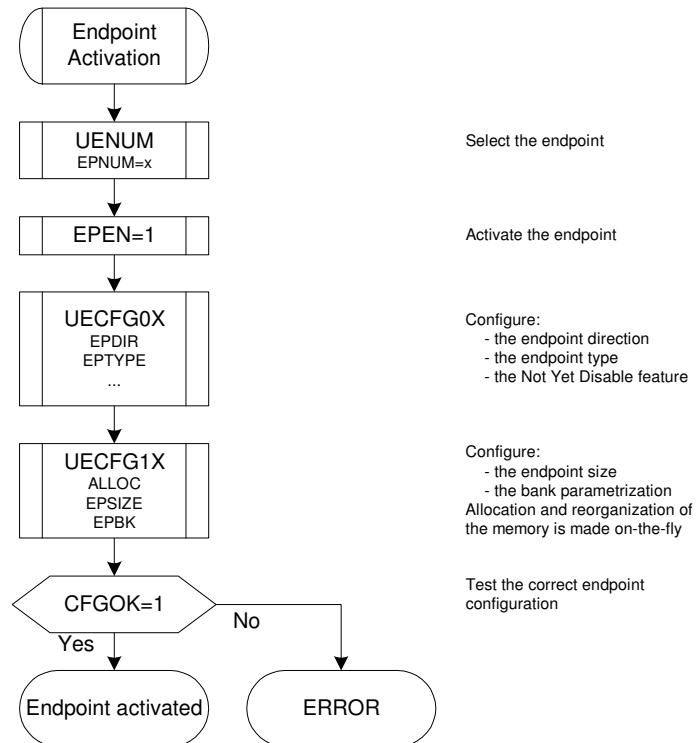

- Set EPNUMS,
- EPNUM = endpoint<sub>x</sub>
- Set DFCDY when the DFC transfer is ready to take place,
- ...<DFC transfer>...
- SETUP received on endpoint<sub>0</sub> (EPINT<sub>0</sub> set, RXSTPI set),

- Clear DFCDY to freeze the DFC transfer,
- If the CPU EPNUM has to be changed: EPNUMS cleared, EPNUM = endpoint<sub>0</sub>
- Read endpoint<sub>0</sub> data (UEDATX)
- Set DFCDY. This resumes the DFC transfer.

## Endpoint Activation

The endpoint is maintained under reset as long as the EPEN bit is not set. The following flow must be respected in order to activate an endpoint:

**Figure 60.** Endpoint activation flow:

As long as the endpoint is not correctly configured (CFGOK cleared), the hardware does not acknowledge the packets sent by the host.

CFGOK is will not be sent if the Endpoint size parameter is bigger than the DPRAM size.

A clear of EPEN acts as an endpoint reset (see Section “Endpoint Reset” for more details). It also performs the next operation:

- The configuration of the endpoint is kept (EPSIZE, EPBK, ALLOC kept)
- It resets the data toggle field.
- The DPRAM memory associated to the endpoint is still reserved.

See Section “Memory Management”, page 90 for more details about the memory allocation/reorganization.

## Address Setup

The USB device address is set up according to the USB protocol:

- the USB device, after power-up, responds at address 0

- the host sends a **SETUP** command (SET\_ADDRESS(addr)),
- the firmware records that address in UADD, but keep ADDEN cleared,
- the USB device sends an **IN** command of 0 bytes (IN 0 Zero Length Packet),
- then, the firmware can enable the USB device address by setting ADDEN. The only accepted address by the controller is the one stored in UADD.

ADDEN and UADD shall not be written at the same time.

UADD contains the default address 00h after a power-up or USB reset.

ADDEN is cleared by hardware:

- after a power-up reset,
- when an USB reset is received,
- or when the macro is disabled (USBE cleared)

When this bit is cleared, the default device address 00h is used.

## Suspend, Wake-Up and Resume

After a period of 3 ms during which the USB line was inactive, the controller switches to the full-speed mode and triggers (if enabled) the SUSPI (suspend) interrupt. The firmware may then set the FRZCLK bit.

The CPU can also, depending on software architecture, enter in the idle mode to lower again the power consumption.

There are two ways to recover from the “Suspend” mode:

- First one is to clear the FRZCLK bit. This is possible if the CPU is not in the Idle mode.
- Second way, if the CPU is “idle”, is to enable the WAKEUPI interrupt (WAKEUPE set). Then, as soon as a non-idle signal is seen by the controller, the WAKEUPI interrupt is triggered. The firmware shall then clear the FRZCLK bit to restart the transfer.

There are no relationship between the SUSPI interrupt and the WAKEUPI interrupt: the WAKEUPI interrupt is triggered as soon as there are non-idle patterns on the data lines. Thus, the WAKEUPI interrupt can occur even if the controller is not in the “suspend” mode.

When the WAKEUPI interrupt is triggered, if the SUSPI interrupt bit was already set, it is cleared by hardware.

When the SUSPI interrupt is triggered, if the WAKEUPI interrupt bit was already set, it is cleared by hardware.

## Detach

The reset value of the DETACH bit is 1.

It is possible to re-enumerate a device, simply by setting and clearing the DETACH bit.

- If the USB device controller is in full-speed mode, setting DETACH will disconnect the pull-up on the D+ or D- pad (depending on full or low speed mode selected). Then, clearing DETACH will connect the pull-up on the D+ or D- pad.

Figure 61. Detach a device in Full-speed:

## Remote Wake-Up

The “Remote Wake-up” (or “upstream resume”) request is the only operation allowed to be sent by the device on its own initiative. Anyway, to do that, the device should first have received a DEVICE\_REMOTE\_WAKEUP request from the host.

- First, the USB controller must have detected the “suspend” state of the line: the remote wake-up can only be sent after a SUSPI interrupt has been triggered.
- The firmware has then the ability to set RMWKUP to send the “upstream resume” stream. This will automatically be done by the controller after 5ms of inactivity on the USB line.
- When the controller starts to send the “upstream resume”, the UPRSMI interrupt is triggered (if enabled). If SUSPI was set, SUSPI is cleared by hardware.
- RMWKUP is cleared by hardware at the end of the “upstream resume”.
- If the controller detects a good “End Of Resume” signal from the host, an EORSMI interrupt is triggered (if enabled).

## STALL Request

For each endpoint, the STALL management is performed using 2 bits:

- STALLRQ (enable stall request)
- STALLRQC (disable stall request)
- STALLI (stall sent interrupt)

To send a STALL handshake at the next request, the STALLRQ request bit has to be set. All following requests will be handshak’ed with a STALL until the STALLRQC bit is set.

Setting STALLRQC automatically clears the STALLRQ bit. The STALLRQC bit is also immediately cleared by hardware after being set by software. Thus, the firmware will never read this bit as set.

Each time the STALL handshake is sent, the STALLI flag is set by the USB controller and the EPINTx interrupt will be triggered (if enabled).

**The incoming packets will be discarded (RXOUTI and RWAL will not be set).**

The host will then send a command to reset the STALL: the firmware just has to set the STALLRQC bit and to reset the endpoint.

## Special Consideration for Control Endpoints

A SETUP request is always ACK’ed.

If a STALL request is set for a Control Endpoint and if a SETUP request occurs, the SETUP request has to be ACK’ed and the STALLRQ request and STALLI sent flags are automatically reset (RXSETUPI set, TXINI cleared, STALLI cleared, TXINI cleared...).

This management simplifies the enumeration process management. If a command is not supported or contains an error, the firmware set the STALL request flag and can return to the main task, waiting for the next SETUP request.

This function is compliant with the Chapter 8 test from PMTC that send extra status for a GET\_DESCRIPTOR. The firmware sets the STALL request just after receiving the status. All extra status will be automatically STALL'ed until the next SETUP request.

### STALL Handshake and Retry Mechanism

The Retry mechanism has priority over the STALL handshake. A STALL handshake is sent if the STALLRQ request bit is set and if there is no retry required.

### CONTROL Endpoint Management

A SETUP request is always ACK'ed. When a new setup packet is received, the RXSTPI interrupt is triggered (if enabled). The RXOUTI interrupt is not triggered.

The FIFOCON and RWAL fields are irrelevant with CONTROL endpoints. The firmware shall thus never use them on that endpoints. When read, their value is always 0.

CONTROL endpoints are managed by the following bits:

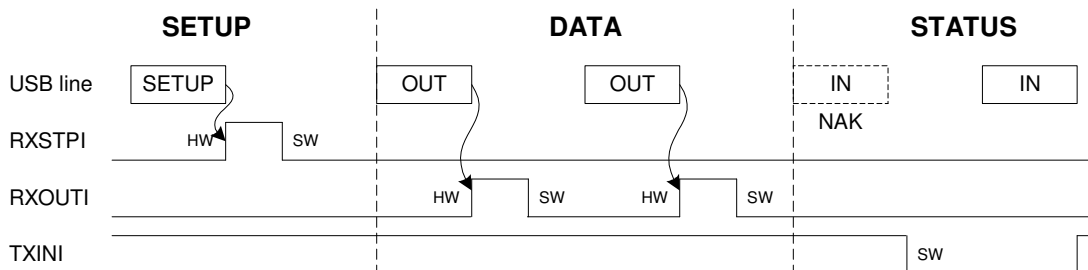

- RXSTPI is set when a new SETUP is received. It shall be cleared by firmware to acknowledge the packet **and to clear the endpoint bank**.
- RXOUTI is set when a new OUT data is received. It shall be cleared by firmware to acknowledge the packet **and to clear the endpoint bank**.
- TXINI is set when the bank is ready to accept a new IN packet. It shall be cleared by firmware to **send the packet and to clear the endpoint bank**.

CONTROL endpoints should not be managed by interrupts, but only by polling the status bits.

### Control Write

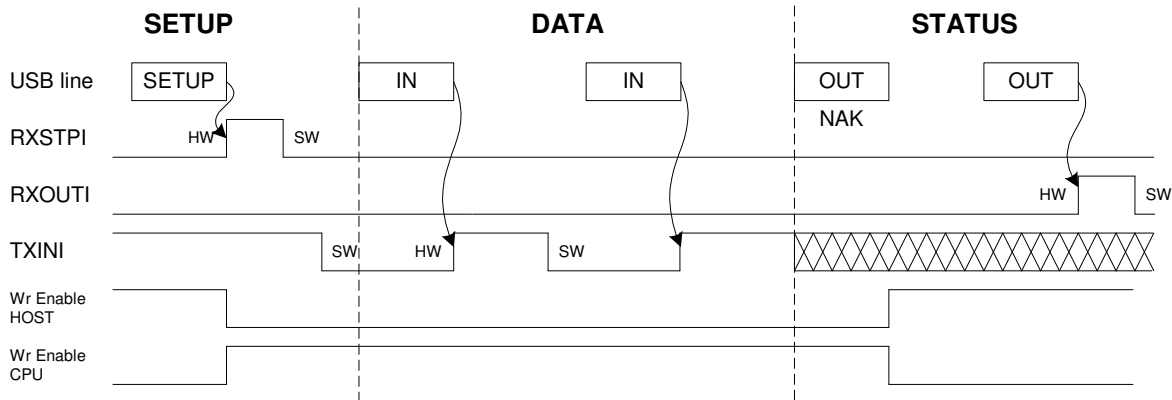

The next figure shows a control write transaction. During the status stage, the controller will not necessary send a NAK at the first IN token:

- If the firmware knows the exact number of descriptor bytes that must be read, it can then anticipate on the status stage and send a ZLP for the next IN token,
- or it can read the bytes and poll NAKINI, which tells that all the bytes have been sent by the host, and the transaction is now in the status stage.

## Control Read

The next figure shows a control read transaction. The USB controller has to manage the simultaneous write requests from the CPU and the USB host:

A NAK handshake is always generated at the first status stage command.

When the controller detect the status stage, all the data written by the CPU are erased, and clearing TXINI has no effects.

The firmware checks if the transmission is complete or if the reception is complete.

The OUT retry is always ack'ed. This reception:

- set the RXOUTI flag (received OUT data)
- set the TXINI flag (data sent, ready to accept new data)

software algorithm:

```

set transmit ready
wait (transmit complete OR Receive complete)
if receive complete, clear flag and return
if transmit complete, continue
    
```

Once the OUT status stage has been received, the USB controller waits for a SETUP request. The SETUP request have priority over any other request and has to be ACK'ed. This means that any other flag should be cleared and the fifo reset when a SETUP is received.

**WARNING:** the byte counter is reset when the OUT Zero Length Packet is received. The firmware has to take care of this.

## OUT Endpoint Management

OUT packets are sent by the host. All the data can be read by the CPU, which acknowledges or not the bank when it is empty.

### Overview

The Endpoint must be configured first.

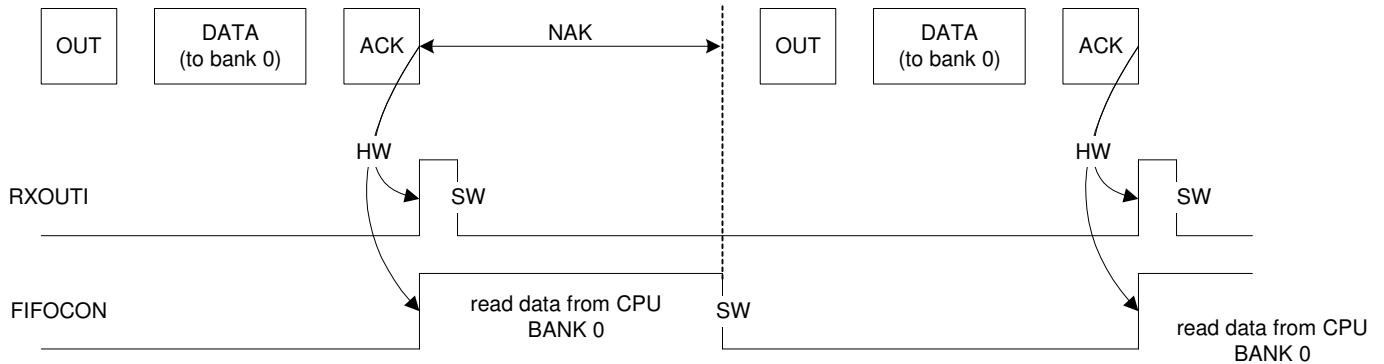

#### "Manual" Mode

Each time the current bank is full, the RXOUTI and the FIFOCON bits are set. This triggers an interrupt if the RXOUTE bit is set. The firmware can acknowledge the USB interrupt by clearing the RXOUTI bit. The Firmware read the data and clear the FIFOCON bit in order to free the current bank. If the OUT Endpoint is composed of multiple

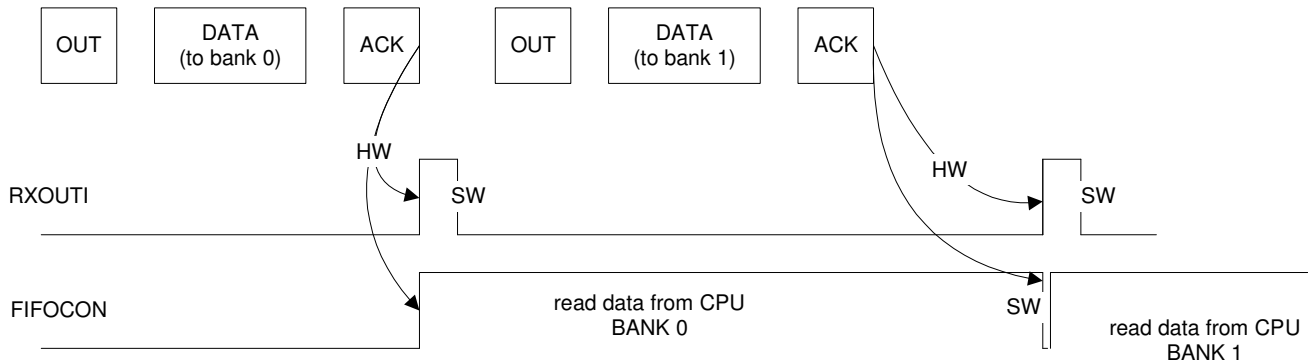

banks, clearing the FIFOCON bit will switch to the next bank. The RXOUTI and FIFOCON bits are then updated by hardware in accordance with the status of the new bank. RXOUTI shall always be cleared before clearing FIFOCON.

The RWAL bit always reflects the state of the current bank. This bit is set if the firmware can read data from the bank, and cleared by hardware when the bank is empty.

Example with 1 OUT data bank

Example with 2 OUT data banks

*“Autoswitch” Mode*

In this mode, the clear of the FIFOCON bit is performed automatically by hardware each time the Endpoint bank is empty. The firmware has to check if the next bank is empty or not before reading the next data. On RXOUTI interrupt, the firmware reads a complete bank. A new interrupt will be generated each time the current bank contains data to read.

The acknowledge of the RXOUTI interrupt is always performed by software.

**Detailed Description**

*standard Mode Without AUTOSW*

In this mode (AUTOSW cleared), the data are read by the CPU, following the next flow:

- When the bank is filled by the host, an endpoint interrupt (EPINTx) is triggered, if enabled (RXOUTE set) and RXOUTI is set. The CPU can also poll RXOUTI or FIFOCON, depending on the software architecture,
- The CPU acknowledges the interrupt by clearing RXOUTI,
- The CPU can read the number of byte (N) in the current bank (N=BYCT),

- The CPU can read the data from the current bank (“N” read of UEDATX),
- The CPU can free the bank by clearing FIFOCON when all the data is read, that is:
  - after “N” read of UEDATX,
  - as soon as RWAL is cleared by hardware.

If the endpoint uses 2 banks, the second one can be filled by the HOST while the current one is being read by the CPU. Then, when the CPU clear FIFOCON, the next bank may be already ready and RXOUTI is set immediately.

### *Standard Mode with AUTOSW*

In this mode (AUTOSW set), the flow operation is the same as Section “standard Mode Without AUTOSW”, page 108, with the exception that the CPU does not have to free the bank (FIFOCON cleared): this will automatically be done when the CPU read the last byte of the bank.

- EPINTx (RXOUTE set, RXOUTI set) or polling on RXOUTI=1 or FIFOCON=1,
- The CPU acknowledges the interrupt by clearing RXOUTI,
- The CPU read the number of byte (N) in the current bank (N=BYCT) (or already knows the number “N” of bytes at each packet),
- The CPU can read the data from the current bank (“N” read of UEDATX, or can read while RWAL is set).

A clear of FIFOCON does not have any effects in this mode.

### *Using the DFC with AUTOSW*

In this mode (AUTOSW set, DFC programmed), the data are handled by the DFC without any intervention from the CPU. The flow is:

- programming of the DFC,
- poll End Of Transfer from the DFC.

The bank switching is automatically done: when a bank is emptied, it is freed and the switch occurs. If the End Of Transfer occurs while the bank is not emptied, the CPU has the responsibility to free it.

The CPU shall not use UEDATX or the byte counter BYCT in this mode. A clear of FIFOCON does not have any effects in this mode.

If a ZLP is received, it will be filtered by the USB device controller, and the flag ZLP-SEEN is set.

### *Using the DFC without AUTOSW*

In this mode (AUTOSW cleared, DFC programmed), the data are handled by the DFC but the CPU have to acknowledge each bank read.

- programming of the DFC,
- EPINTx (RXOUTE set, RXOUTI set) or polling on RXOUTI=1 or FIFOCON=1,
- The CPU acknowledges the interrupt by clearing RXOUTI,
- poll the wait of the transfer: (while RWAL is set: wait),
- Clear FIFOCON which frees the bank and switch to the next one.

## **IN Endpoint Management**

IN packets are sent by the USB device controller, upon an IN request from the host. All the data can be written by the CPU, which acknowledge or not the bank when it is full.

### **Overview**

The Endpoint must be configured first.

### *“Manual” Mode*

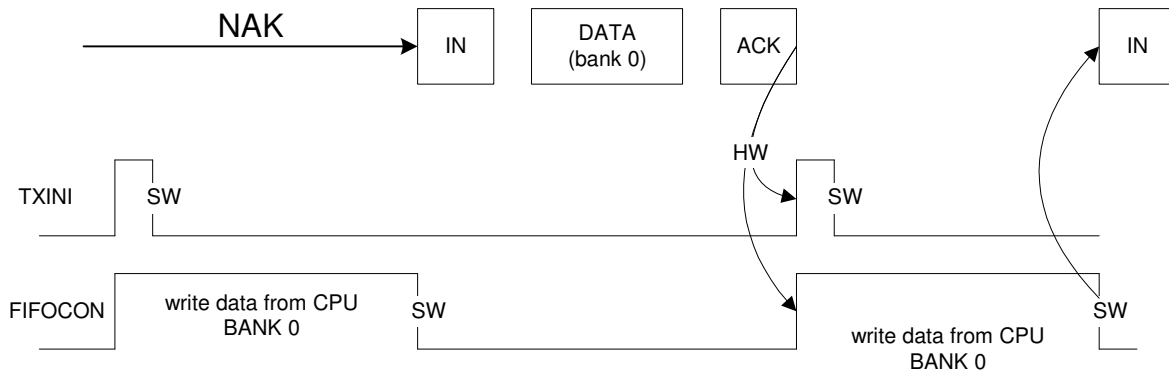

The TXINI bit is set by hardware when the current bank becomes free. This triggers an interrupt if the TXINE bit is set. The FIFOCON bit is set at the same time. The CPU

writes into the FIFO and clears the FIFOCON bit to allow the USB controller to send the data. If the IN Endpoint is composed of multiple banks, this also switches to the next data bank. The TXINI and FIFOCON bits are automatically updated by hardware regarding the status of the next bank.

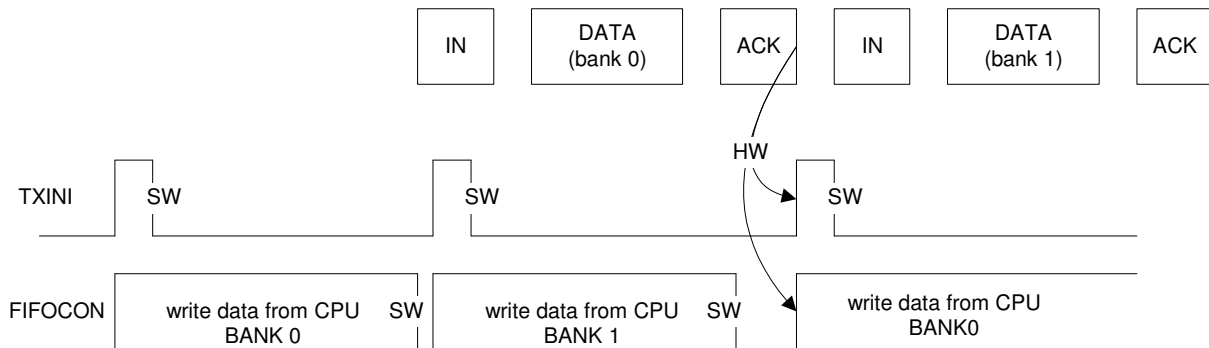

TXINI shall always be cleared before clearing FIFOCON.

The RWAL bit always reflects the state of the current bank. This bit is set if the firmware can write data to the bank, and cleared by hardware when the bank is full.

Example with 1 IN data bank

Example with 2 IN data banks

*“Autoswitch” Mode*

In this mode, the clear of the FIFOCON bit is performed automatically by hardware each time the Endpoint bank is full. The firmware has to check if the next bank is empty or not before writing the next data. On TXINI interrupt, the firmware fills a complete bank. A new interrupt will be generated each time the current bank becomes free.

**Detailed Description**

*Standard Mode without AUTOSW*

In this mode (AUTOSW cleared), the data are written by the CPU, following the next flow:

- When the bank is empty, an endpoint interrupt (EPINTx) is triggered, if enabled (TXINE set) and TXINI is set. The CPU can also poll TXINI or FIFOCON, depending the software architecture choice,
- The CPU acknowledges the interrupt by clearing TXINI,
- The CPU can write the data into the current bank (write in UEDATX),

- The CPU can free the bank by clearing FIFOCON when all the data are written, that is:
  - after “N” write into UEDATX
  - as soon as RWAL is cleared by hardware.

If the endpoint uses 2 banks, the second one can be read by the HOST while the current is being written by the CPU. Then, when the CPU clears FIFOCON, the next bank may be already ready (free) and TXINI is set immediately.

### *Standard Mode with AUTOSW*

In this mode (AUTOSW set), the flow operation is the same as Section “Standard Mode without AUTOSW”, page 110, with the exception that the CPU does not have to free the bank (FIFOCON cleared): this will automatically be done when the CPU fills the bank.

- EPINTx (TXINE set, TXINI set) or polling on TXINI=1 or FIFOCON=1,
- The CPU acknowledges the interrupt by clearing TXINI,
- The CPU can write the data to the current bank (write in UEDATX) while RWAL is set.

A clear of FIFOCON does not have any effects in this mode.

### *Using the DFC with AUTOSW*

In this mode (AUTOSW set, DFC programmed), the data are handled by the DFC without any intervention from the CPU. The flow is:

- programming of the DFC,
- poll End Of Transfer from the DFC.

The bank switching is automatically done: when a bank is filled, it is freed and the switch occurs. If the End Of Transfer occurs while the bank is not filled, the CPU has the responsibility to free it.

The CPU shall not use UEDATX or the byte counter BYCT in this mode. A clear of FIFOCON does not have any effects in this mode.

### *Using the DFC without AUTOSW*

In this mode (AUTOSW=0, DFC programmed), the data are handled by the DFC but the CPU have to acknowledge each bank written:

- programming of the DFC,
- EPINTx (TXINE set, TXINI set) or polling on TXINI=1 or FIFOCON=1,
- The CPU acknowledges the interrupt by clearing TXINI,
- poll the wait of the transfer: (while RWAL is set: wait),
- Clear FIFOCON which frees the bank and switch to the next one.

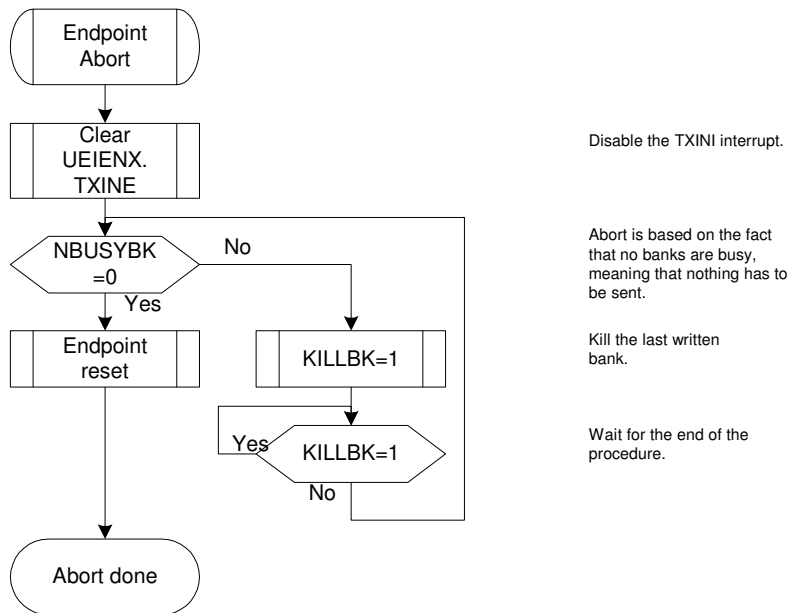

### *Abort*

An “abort” stage can be produced by the host in some situations:

- In a control transaction: ZLP data OUT received during a IN stage,
- In an isochronous IN transaction: ZLP data OUT received on the OUT endpoint during a IN stage on the IN endpoint
- ...

The KILLBK bit is used to kill the last “written” bank. The best way to manage this abort is to perform the following operations:

**Table 111.** Abort flow

## Isochronous Mode

For Isochronous IN endpoints, it is possible to automatically switch the banks on each start of frame (SOF). This is done by setting ISOSW. The CPU has to fill the bank of the endpoint; the bank switching will be automatic as soon as a SOF is seen by the hardware.

A clear of FIFOCON does not have any effects in this mode.

In the case that a SOF is missing (noise on USB pad, ...), the controller will automatically build internally a “pseudo” start of frame and the bank switching is made. The SOFI interrupt is triggered and the frame number FNUM10:0 is increased.

## Underflow

An underflow can occur during IN stage if the host attempts to read a bank which is empty. In this situation, the UNDERFI interrupt is triggered.

An underflow can also occur during OUT stage if the host send a packet while the banks are already full. Typically, he CPU is not fast enough. The packet is lost.

It is not possible to have underflow error during OUT stage, in the CPU side, since the CPU should read only if the bank is ready to give data (RXOUTI=1 or RWAL=1)

## CRC Error

A CRC error can occur during OUT stage if the USB controller detects a bad received packet. In this situation, the STALLI interrupt is triggered. This does not prevent the RXOUTI interrupt from being triggered.

## Overflow

In Control, Isochronous, Bulk or Interrupt Endpoint, an overflow can occur during OUT stage, if the host attempts to write in a bank that is too small for the packet. In this situation, the OVERFI interrupt is triggered (if enabled). The packet is acknowledged and the RXOUTI interrupt is also triggered (if enabled). The bank is filled with the first bytes of the packet.

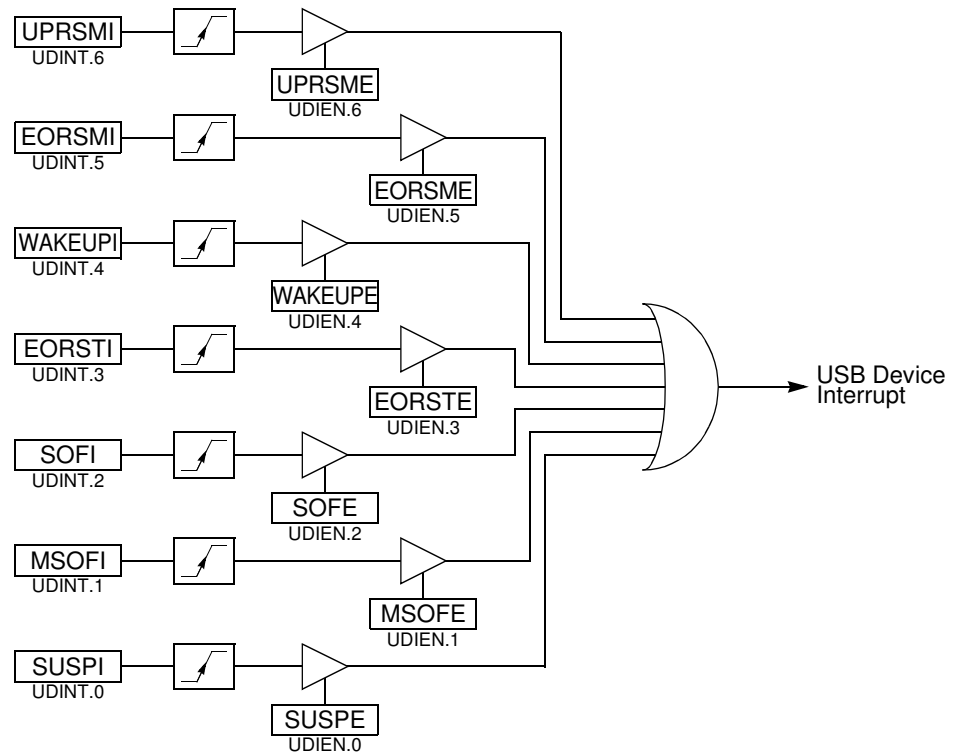

It is not possible to have overflow error during IN stage, in the CPU side, since the CPU should write only if the bank is ready to access data (TXINI=1 or RWAL=1).

Interrupts

Figure 62 shows all the device interrupts sources while Figure 63 details the endpoint interrupt sources.

Figure 62. USB Device Controller Interrupt System

There are 2 kinds of interrupts: processing (i.e. their generation are part of the normal processing) and exception (errors).

Processing interrupts are generated when the following events are triggered:

- VBUSTI: VBUS plug-in detection (insert, remove)
- UPRSMI: upstream resume
- EORSMI: end of resume
- WAKEUPI: Wake up
- EORSTI: end of reset (Speed Initialization)
- SOFI: start of frame (FNCERR= 0)
- MSOFI: micro start of frame (FNCERR= 0)
- SUSPI: suspend detected after 3 ms of inactivity

Exception Interrupts are generated when the following events are triggered:

- SOFI: CRC error in frame number of SOF (FNCERR= 1)
- MSOFI: CRC error in frame number of micro-SOF (FNCERR= 1)

**Figure 63.** USB Device Controller Endpoint Interrupt System

Processing interrupts are generated when the following events are triggered:

- TXINI: ready to accept IN data
- RXOUTI: OUT data received
- RXSTPI: SETUP received

Exception Interrupts are generated when the following events are triggered:

- STALLI: stalled packet
- STALLI: CRC error on OUT in isochronous mode
- OVERFI: overflow in isochronous mode
- UNDERFI: underflow in isochronous mode
- NAKINI: NAK IN sent
- NAKOUTI: NAK OUT sent

Registers

USB Device General Registers

**Table 112.** UDCON Register

UDCON (1.D9h) – USB Device General Control Register

7	6	5	4	3	2	1	0
-	-	-	-	-	-	RMWKUP	DETACH
Bit Number	Bit Mnemonic	Description					
7-2	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
1	RMWKUP	<b>Remote Wake-up Bit</b> Set to send an “upstream-resume” to the host for a remote wake-up. Cleared by hardware. Clearing by software has no effect. See Section “Remote Wake-Up” for more details.					
0	DETACH	<b>Detach Bit</b> Set to physically detach de device. Clear to reconnect the device. See Section “Detach” for more details.					

Reset Value = 0000 0001b

**Table 113.** UDINT Register

UDINT (1.D8h) – USB Device Global Interrupt Register

7	6	5	4	3	2	1	0
-	UPRSMI	EORSMI	WAKEUPI	EORSTI	SOFI	MSOFI	SUSPI
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
6	UPRSMI	<b>Upstream Resume Interrupt Flag</b> Set by hardware when the USB controller is sending a resume signal called “Upstream Resume”. This triggers an USB interrupt if UPRSME is set. Shall be cleared by software (USB clocks must be enabled before). Setting by software has no effect.					
5	EORSMI	<b>End Of Resume Interrupt Flag</b> Set by hardware when the USB controller detects a good “End Of Resume” signal initiated by the host. This triggers an USB interrupt if EORSME is set. Shall be cleared by software. Setting by software has no effect.					
4	WAKEUPI	<b>Wake-up CPU Interrupt Flag</b> Set by hardware when the USB controller is re-activated by a filtered non-idle signal from the lines (not by an upstream resume). This triggers an interrupt if WAKEUPE is set. Shall be cleared by software (USB clock inputs must be enabled before). Setting by software has no effect. See Section “Suspend, Wake-Up and Resume” for more details.					

Bit Number	Bit Mnemonic	Description
3	EORSTI	<b>End Of Reset Interrupt Flag</b> Set by hardware when an “End Of Reset” has been detected by the USB controller. This triggers an USB interrupt if EORSTE is set. Shall be cleared by software. Setting by software has no effect.
2	SOFI	<b>Start Of Frame Interrupt Flag</b> Set by hardware when an USB “Start Of Frame” PID (SOF) has been detected (every 1 ms). This triggers an USB interrupt if SOFE is set.
1	MSOFI	<b>Micro-Start Of Frame Interrupt Flag</b> Set by hardware when an USB “Micro-Start Of Frame” PID ( $\mu$ SOF) has been detected (every 125 $\mu$ s). This triggers an USB interrupt if MSOFE is set.
0	SUSPI	<b>Suspend Interrupt Flag</b> Set by hardware when an USB “Suspend” ‘idle bus for 3 frame periods: a J state for 3 ms) is detected. This triggers an USB interrupt if SUSPE is set. Shall be cleared by software. Setting by software has no effect. See Section “Suspend, Wake-Up and Resume” for more details.

Reset Value = 0000 0000b

**Table 114.** UDIEN Register

UDIEN (1.DAh) – USB Device Global Interrupt Enable Register

7	6	5	4	3	2	1	0
-	UPRSME	EORSME	WAKEUPE	EORSTE	SOFE	MSOFE	SUSPE
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
6	UPRSME	<b>Upstream Resume Interrupt Enable Bit</b> Set to enable the UPRSMI interrupt. Clear to disable the UPRSMI interrupt.					
5	EORSME	<b>End Of Resume Interrupt Enable Bit</b> Set to enable the EORSMI interrupt. Clear to disable the EORSMI interrupt.					
4	WAKEUPE	<b>Wake-Up CPU Interrupt Enable Bit</b> Set to enable the WAKEUPI interrupt. Clear to disable the WAKEUPI interrupt.					
3	EORSTE	<b>End Of Reset Interrupt Enable Bit</b> Set to enable the EORSTI interrupt. This bit is set after a reset. Clear to disable the EORSTI interrupt.					
2	SOFE	<b>Start Of Frame Interrupt Enable Bit</b> Set to enable the SOFI interrupt. Clear to disable the SOFI interrupt.					
1	MSOFE	<b>Micro-Start Of Frame Interrupt Enable Bit</b> Set to enable the MSOFI interrupt. Clear to disable the MSOFI interrupt.					

Bit Number	Bit Mnemonic	Description
0	SUSPE	<b>Suspend Interrupt Enable Bit</b> Set to enable the SUSPI interrupt. Clear to disable the SUSPI interrupt.

Reset Value = 0000 0000b

**Table 115.** UDADDR Register

UDADDR (1.DBh) – USB Device Address Register

7	6	5	4	3	2	1	0
ADDEN	UADD6	UADD5	UADD4	UADD3	UADD2	UADD1	UADD0

Bit Number	Bit Mnemonic	Description
7	ADDEN	<b>Address Enable Bit</b> Set to activate the UADD (USB address). Cleared by hardware. Clearing by software has no effect. See Section “Address Setup” for more details.
6-0	UADD6:0	<b>USB Address Bits</b> Set to configure the device address. Shall not be cleared.

Reset Value = 0000 0000b

**Table 116.** UDFNUMH Register

UDFNUMH (1.DCh) – USB Device Frame Number High Register

7	6	5	4	3	2	1	0
-	-	-	-	-	FNUM10	FNUM9	FNUM8

Bit Number	Bit Mnemonic	Description
7-3	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
2-0	FNUM10:8	<b>Frame Number Upper Flag</b> Set by hardware. These bits are the 3 MSB of the 11-bits Frame Number information. They are provided in the last received SOF packet. FNUM is updated if a corrupted SOF is received.

Reset Value = 0000 0000b

**Table 117.** UDFNUML Register

UDFNUML (1.DDh) – USB Device Frame Number Low Register

7	6	5	4	3	2	1	0
FNUM7	FNUM6	FNUM5	FNUM4	FNUM3	FNUM2	FNUM1	FNUM0

Bit Number	Bit Mnemonic	Description
7-0	FNUM7:0	<b>Frame Number Lower Flag</b> Set by hardware. These bits are the 8 LSB of the 11-bits Frame Number information.

Reset Value = 0000 0000b

**Table 118.** UDMFN Register

UDMFN (1.DEh) – USB Device Frame Number Register

7	6	5	4	3	2	1	0
-	-	-	FNCERR	-	MFNUM2:0		

Bit Number	Bit Mnemonic	Description
7-5	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
4	FNCERR	<b>Frame Number CRC Error Flag</b> Set by hardware when a corrupted Frame Number in start of frame packet is received. This bit and the SOFI interrupt are updated at the same time.
3	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.
2-0	MFNUM2:0	<b>Micro-Frame Number Flag</b> Number of micro-frames (0 to 7) received in one frame. MFNUM is reset at the beginning of each new frame (every 1 ms).

Reset Value = 0000 0000b

## USB Device Endpoint Registers

**Table 119.** UENUM Register

UENUM (1.C9h) – USB Endpoint Number Selection Register

7	6	5	4	3	2	1	0
-	-	-	-	-	EPNUM2	EPNUM1	EPNUM0

Bit Number	Bit Mnemonic	Description
7-3	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
2-0	EPNUM2:0	<b>Endpoint Number Bits</b> Set to select the number of the endpoint which shall be accessed by the CPU or by the DFC depending on UPNUMS bit in UECONX. See Section "Endpoint Selection" for more details. EPNUM = 111b is forbidden.

Reset Value = 0000 0000b

**Table 120.** UERST Register

UERST (1.CAh) – USB Endpoint Reset Register

7	6	5	4	3	2	1	0
-	EPRST6	EPRST5	EPRST4	EPRST3	EPRST2	EPRST1	EPRST0
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
6-0	EPRST6:0	<b>Endpoint FIFO Reset Bits</b> Set to reset the selected endpoint FIFO prior to any other operation, upon hardware reset or when an USB bus reset has been received. See Section "Endpoint Reset" for more information. Then, cleared by software to complete the reset operation and start using the FIFO.					

Reset Value = 0000 0000b

**Table 121.** UECONX Register

UECONX (1.CBh) – USB Endpoint Control Register

7	6	5	4	3	2	1	0
-	-	STALLRQ	STALLRQC	RSTDT	EPNUMS	DFCRDY	EPEN
Bit Number	Bit Mnemonic	Description					
7-6	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
5	STALLRQ	<b>STALL Request Handshake Bit</b> Set to request a STALL answer to the host for the next handshake. Cleared by hardware when a new SETUP is received. Clearing by software has no effect. See Section "STALL Request" for more details.					
4	STALLRQC	<b>STALL Request Clear Handshake Bit</b> Set to disable the STALL handshake mechanism. Cleared by hardware immediately after the set. Clearing by software has no effect. See Section "STALL Request" for more details.					
3	RSTDT	<b>Reset Data Toggle Bit</b> Set to automatically clear the data toggle sequence: For OUT endpoint: the next received packet will have the data toggle 0. For IN endpoint: the next packet to be sent will have the data toggle 0. Cleared by hardware instantaneously. The firmware does not have to wait that the bit is cleared. Clearing by software has no effect.					
2	EPNUMS	<b>Endpoint Number Select Bit</b> Set to configure the EPNUM used by the DFC. Clear to select the EPNUM used by the CPU.					
1	DFCRDY	<b>DFC Ready Bit</b> Set to resume/enable the DFC interface. Clear to pause the DFC interface.					

Bit Number	Bit Mnemonic	Description
0	EPEN	<b>Endpoint Enable Bit</b> Set to enable the endpoint according to the device configuration. Endpoint 0 shall always be enabled after a hardware or USB reset and participate in the device configuration. Clear this bit to disable the endpoint. See Section “Endpoint Activation” for more details.

Reset Value = 0000 0000b

**Table 122.** UECFG0X Register

UECFG0X (1.CCh) – USB Endpoint Configuration 0 Register

7	6	5	4	3	2	1	0
EPTYPE1:0	-	-	ISOSW	AUTOSW	NYETDIS	EPDIR	

Bit Number	Bit Mnemonic	Description
7-6	EPTYPE1:0	<b>Endpoint Type Bits</b> Set this bit according to the endpoint configuration: 00b: Control      10b: Bulk 01b: Isochronous    11b: Interrupt
5-4	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
3	ISOSW	<b>Isochronous Switch Bit</b> Set to automatically switch banks on each SOF. Clear to disable the automatic bank switching on each SOF. See Section “Isochronous Mode” for more details.
2	AUTOSW	<b>Automatic Switch Bit</b> Set to automatically switch bank when it is ready. Clear to disable the automatic bank switching. See Section “OUT Endpoint Management” and Section “IN Endpoint Management” for more details.
1	NYETDIS	<b>Not Yet Disable Bit</b> Set to automatically send a “ACK” handshake instead of “Not Yet” handshake. Thus, the host will not have to “ping” for the next packet. Clear to automatically send “Not Yet” handshake. Thus, the host will have to “ping” for the next packet.
0	EPDIR	<b>Endpoint Direction Bit</b> Set to configure an IN direction for bulk, interrupt or isochronous endpoints. Clear to configure an OUT direction for bulk, interrupt, isochronous or control endpoints.

Reset Value = 0000 0000b

**Table 123.** UECFG1X Register

UECFG1X (1.CDh) – USB Endpoint Configuration 1 Register

7	6	5	4	3	2	1	0
-	EPSIZE2	EPSIZE1	EPSIZE0	EPBK1	EPBK	ALLOC	-

Bit Number	Bit Mnemonic	Description
7	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
6-4	EPSIZE2:0	<b>Endpoint Size Bits</b> Set this bit according to the endpoint size: 000b: 8 bytes      100b: 128 bytes 001b: 16 bytes     101b: 256 bytes 010b: 32 bytes     110b: 512 bytes 011b: 64 bytes     111b: Reserved. Do not use this configuration.
3-2	EPBK1:0	<b>Endpoint Bank Bits</b> Set this field according to the endpoint size: 00b: Single bank 01b: Double bank 1xb: Reserved. Do not use this configuration.
1	ALLOC	<b>Endpoint Allocation Bit</b> Set this bit to allocate the endpoint memory. Clear to free the endpoint memory. See Section "Endpoint Activation" for more details.
0	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.

Reset Value = 0000 0000b

**Table 124.** UESTA0X Register

UESTA0X (1.CEh) – USB Endpoint Status 0 Register

7	6	5	4	3	2	1	0
CFGOK	OVERFI	UNDERFI	ZLPSEEN	DTSEQ1	DTSEQ0	NBUSYBK1	NBUSYBK0
Bit Number	Bit Mnemonic	Description					
7	CFGOK	<b>Configuration Status Flag</b> Set by hardware when the endpoint X size parameter (EPSIZE) and the bank parametrization (EPBK) are correct compared to the max FIFO capacity and the max number of allowed bank. This bit is updated when the bit ALLOC is set. If this bit is cleared, the user should reprogram the UECFG1X register with correct EPSIZE and EPBK values.					
6	OVERFI	<b>Overflow Error Interrupt Flag</b> Set by hardware when an overflow error occurs in an isochronous endpoint. An interrupt (EPINTx) is triggered (if enabled). See Section "Isochronous Mode" for more details. Shall be cleared by software. Setting by software has no effect.					
5	UNDERFI	<b>Flow Error Interrupt Flag</b> Set by hardware when an underflow error occurs in an isochronous endpoint. An interrupt (EPINTx) is triggered (if enabled). See Section "Isochronous Mode" for more details. Shall be cleared by software. Setting by software has no effect.					
4	ZLPSEEN	<b>Zero Length Packet Seen (bit / Flag)</b> Set by hardware, as soon as a ZLP has been filtered during a transfer. Shall be cleared by the software. Setting by software has no effect.					

Bit Number	Bit Mnemonic	Description
3-2	DTSEQ1:0	<b>Data Toggle Sequencing Flag</b> Set by hardware to indicate the PID data of the current bank: 00b: Data0 01b: Data1 1xb: Reserved. For OUT transfer, this value indicates the last data toggle received on the current bank. For IN transfer, it indicates the Toggle that will be used for the next packet to be sent. This is not relative to the current bank.
1-0	NBUSYBK1:0	<b>Busy Bank Flag</b> Set by hardware to indicate the number of busy bank. For IN endpoint, it indicates the number of busy bank(s), filled by the user, ready for IN transfer. For OUT endpoint, it indicates the number of busy bank(s) filled by OUT transaction from the host. 00b: All banks are free 01b: 1 busy bank 10b: 2 busy banks 11b: Reserved.

Reset Value = 0000 0000b

**Table 125.** UESTA1X Register

UESTA1X (1.CFh) – USB Endpoint Status 1 Register

7	6	5	4	3	2	1	0
-	-	-	-	-	CTRLDIR	CURRBK1	CURRBK0

Bit Number	Bit Mnemonic	Description
7-3	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
2	CTRLDIR	<b>Control Direction (Flag, and bit for debug purpose)</b> Set by hardware after a SETUP packet, and gives the direction of the following packet: - 1 for IN endpoint - 0 for OUT endpoint. Can not be set or cleared by software.
1-0	CURRBK1:0	<b>Current Bank (all endpoints except Control endpoint) Flag</b> Set by hardware to indicate the number of the current bank: 00b: Bank0 01b: Bank1 1xb: Reserved. Can not be set or cleared by software.

Reset Value = 0000 0000b

**Table 126.** UEINTX Register (bit addressable)

UEINTX (1.C8h) – USB Endpoint Interrupt Register

7	6	5	4	3	2	1	0
FIFOCON	NAKINI	RWAL	NAKOUTI	RXSTPI	RXOUTI	STALLI	TXINI
Bit Number	Bit Mnemonic	Description					
7	FIFOCON	<p><b>FIFO Control Bit</b>                      For OUT and SETUP Endpoint:                      Set by hardware when a new OUT message is stored in the current bank, at the same time than RXOUT or RXSTP.                      Clear to free the current bank and to switch to the following bank. Setting by software has no effect.</p> <p>For IN Endpoint:                      Set by hardware when the current bank is free, at the same time than TXIN.                      Clear to send the FIFO data and to switch the bank. Setting by software has no effect.</p>					
6	NAKINI	<p><b>NAK IN Received Interrupt Flag</b>                      Set by hardware when a NAK handshake has been sent in response of a IN request from the host. This triggers an USB interrupt if NAKINE is sent.                      Shall be cleared by software. Setting by software has no effect.</p>					
5	RWAL	<p><b>Read/Write Allowed Flag</b>                      Set by hardware to signal:                      - for an IN endpoint: the current bank is not full i.e. the firmware can push data into the FIFO,                      - for an OUT endpoint: the current bank is not empty, i.e. the firmware can read data from the FIFO.                      The bit is never set if STALLRQ is set, or in case of error.                      Cleared by hardware otherwise.                      This bit shall not be used for the control endpoint.</p>					
4	NAKOUTI	<p><b>NAK OUT Received Interrupt Flag</b>                      Set by hardware when a NAK handshake has been sent in response of a OUT/PING request from the host. This triggers an USB interrupt if NAKOUTE is sent.                      Shall be cleared by software. Setting by software has no effect.</p>					
3	RXSTPI	<p><b>Received SETUP Interrupt Flag</b>                      Set by hardware to signal that the current bank contains a new valid SETUP packet. An interrupt (EPINTx) is triggered (if enabled).                      Shall be cleared by software to acknowledge the interrupt. Setting by software has no effect.                      This bit is inactive (cleared) if the endpoint is an IN endpoint.</p>					
2	RXOUTI / KILLBK	<p><b>Received OUT Data Interrupt Flag</b>                      Set by hardware to signal that the current bank contains a new packet. An interrupt (EPINTx) is triggered (if enabled).                      Shall be cleared by software to acknowledge the interrupt. Setting by software has no effect.</p> <p><b>Kill Bank IN Bit</b>                      Set this bit to kill the last written bank.                      Cleared by hardware when the bank is killed. Clearing by software has no effect.                      See Section "Abort" for more details on the Abort.</p>					

Bit Number	Bit Mnemonic	Description
1	STALLI	<b>Stall Interrupt Flag</b> Set by hardware to signal that a STALL handshake has been sent, or that a CRC error has been detected in a OUT isochronous endpoint. Shall be cleared by software. Setting by software has no effect.
0	TXINI	<b>Transmitter Ready Interrupt Flag</b> Set by hardware to signal that the current bank is free and can be filled. An interrupt (EPINTx) is triggered (if enabled). Shall be cleared by software to acknowledge the interrupt. Setting by software has no effect. This bit is inactive (cleared) if the endpoint is an OUT endpoint.

Reset Value = 0000 0000b

7	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
6-0	EPINT6:0	<b>Endpoint Interrupts Bits</b> Set by hardware when an interrupt is triggered by the UEINTX register and if the corresponding endpoint interrupt enable bit is set. Cleared by hardware when the interrupt source is served.					

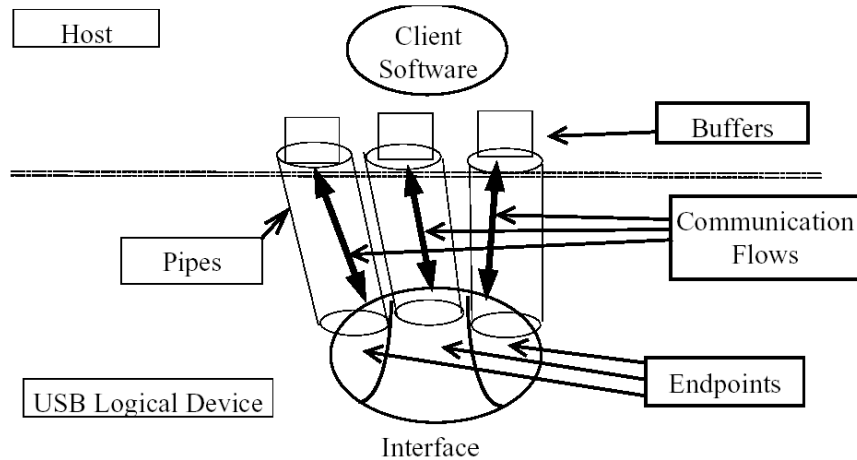

Reset Value = 0000 0000b.

## USB Host Operating Modes

### Pipe Description

For the USB Host controller, the term of Pipe is used instead of Endpoint for the USB Device controller (see Figure 64). A Host Pipe corresponds to a Device Endpoint, as described in the USB specification.

**Figure 64.** Pipes and Endpoints in a USB system

In the USB host controller, a Pipe will be associated to a Device Endpoint, considering the Device Configuration Descriptors.

### Detach

The reset value of the DETACH bit is 1. Thus, the firmware has the responsibility of clearing this bit before switching to the Host mode (HOST set).

### Power-on and Reset

Figure 65 shows the USB host controller main states after power-on.

**Figure 65.** USB Host Controller Reset State Machine

USB host controller state after an hardware reset is 'Reset'. When the USB controller is enabled and the USB Host controller is selected, the USB controller is in 'Idle' state. In this state, the USB Host controller waits for the Device connection, **with a minimum power consumption**. The USB Pad should be in Idle mode. The macro does not need to have the PLL activated to enter in 'Host Ready' state.

The Host controller enters in Suspend state when the USB bus is in Suspend state, i.e. when the Host controller doesn't generate the Start of Frame. In this state, the USB consumption is minimum. The Host controller exits to the Suspend state when starting to generate the SOF over the USB line.

## Device Detection

A Device is detected by the USB controller when the USB bus is different from D+ and D- low. In other words, when the USB Host Controller detects the Device pull-up on the D+ line. To enable this detection, the Host Controller has to provide the Vbus power supply to the Device.

The Device Disconnection is detected by the USB Host controller when the USB Idle correspond to D+ and D- low on the USB line.

## Pipe Selection

Prior to any operation performed by the CPU, the Pipe must first be selected. This is done by:

- Clearing PNUMS.
- Setting PNUM with the Pipe number which will be managed by the CPU.

The CPU can then access to the various Pipe registers and data.

In the same manner, if the Pipe must be accessed by the DFC, it must first be selected. This is done by:

- Setting PNUMS.
- Setting PNUM with the Pipe number which will be managed by the DFC.
- Setting DFCDY when the data-flow is ready to take place.

The DFC can then access to the banks (read / write).

The controller internally keeps in memory the PNUM for the CPU and the PNUM for the DFC. In fact, there are 2 PNUM registers multiplexed by the PNUMS bit. Each of them can be read or written by the CPU.

These two registers permits to easily switch from a Pipe under DFC data transfer to the default control Pipe when a SETUP has to be sent, without reprogramming the EPNUM register:

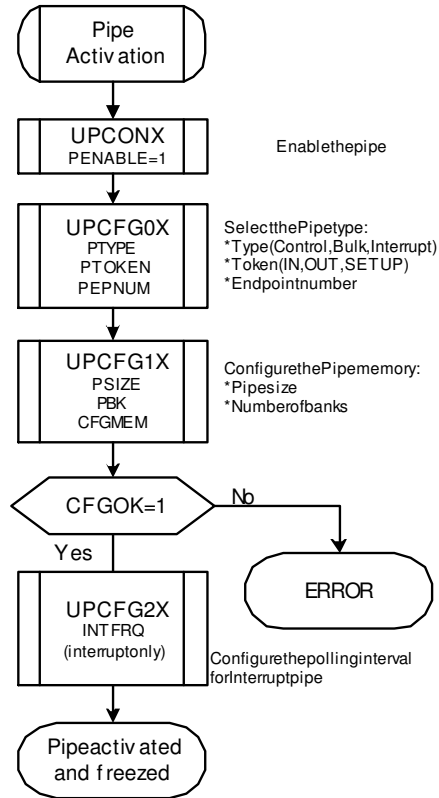

- Set PNUMS,
- $PNUM = Pipe_x$
- Set DFCDY when the DFC transfer is ready to take place,
- ...<DFC transfer>...
- SETUP required on  $Pipe_0$ ,
- Clear DFCDY to freeze the DFC transfer,
- PNUMS cleared,
- $PNUM = Pipe_0$
- Manage  $Pipe_0$  data
- Set DFCDY. This resumes the DFC transfer.

Pipe Configuration

The following flow must be respected in order to activate a Pipe:

Figure 66. Pipe activation flow:

Once the Pipe is activated (EPEN set) and, the hardware is ready to send requests to the Device.

When configured (CFGOK = 1), only the Pipe Token (PTOKEN) and the polling interval for Interrupt pipe can be modified.

A Control type pipe supports only 1 bank. Any other value will lead to a configuration error (CFGOK = 0).

A clear of PEN will reset the configuration of the Pipe. All the corresponding Pipe registers are reset to there reset values. Please refers to the Memory Management chapter for more details.

Note: The firmware has to configure the Default Control Pipe with the following parameters:

- Type: Control
- Token: SETUP
- Data bank: 1
- Size: 64 Bytes

The firmware asks for 8 bytes of the Device Descriptor sending a GET\_DESCRIPTOR request. These bytes contains the MaxPacketSize of the Device default control endpoint and the firmware re-configures the size of the Default Control Pipe with this size parameter.

## USB Reset

The USB controller sends a USB Reset when the firmware set the RESET bit. The RSTI bit is set by hardware when the USB Reset has been sent. This triggers an interrupt if the RSTE has been set.

When a USB Reset has been sent, all the Pipe configuration and the memory allocation are reset. The General Host interrupt enable register is left unchanged.

If the bus was previously in suspend mode (SOFE = 0), the USB controller automatically switches to the resume mode (HWUPI is set) and the SOFE bit is set by hardware in order to generate SOF immediately after the USB Reset.

## Address Setup

Once the Device has answer to the first Host requests with the default address (0), the Host assigns a new address to the device. The Host controller has to send a USB reset to the device and perform a SET ADDRESS control request, with the new address to be used by the Device. This control request ended, the firmware write the new address into the UHADDR register. All following requests, on every Pipes, will be performed using this new address.

When the Host controller send a USB reset, the UHADDR register is reset by hardware and the following Host requests will be performed using the default address (0).

## Remote Wake-Up Detection

The Host Controller enters in Suspend mode when clearing the SOFE bit. No more Start Of Frame is sent on the USB bus and the USB Device enters in Suspend mode 3ms later.

The Device awakes the Host Controller by sending an Upstream Resume (Remote Wake-Up feature). The Host Controller detects a non-idle state on the USB bus and set the HWUPI bit. If the non-Idle correspond to an Upstream Resume (K state), the RXRSML bit is set by hardware. The firmware has to generate a downstream resume within 1ms and for at least 20ms by setting the RESUME bit.

Once the downstream Resume has been generated, the SOFE bit is automatically set by hardware in order to generate SOF immediately after the USB resume.

## USB Pipe Reset

The firmware can reset a Pipe using the pipe reset register. The configuration of the pipe and the data toggle remains unchanged. Only the bank management and the status bits are reset to their initial values.

To completely reset a Pipe, the firmware has to disable and then enable the pipe.

## Pipe Data Access

In order to read or to write into the Pipe Fifo, the CPU selects the Pipe number with the UPNUM register and performs read or write action on the UPDATX register.

## Control Pipe Management

A Control transaction is composed of 3 phases:

- SETUP
- Data (IN or OUT)
- Status (OUT or IN)

The firmware has to change the Token for each phase.

The initial data toggle is set for the corresponding token (ONLY for Control Pipe):

- SETUP: Data0
- OUT: Data1
- IN: Data1 (expected data toggle)

## **OUT Pipe Management**

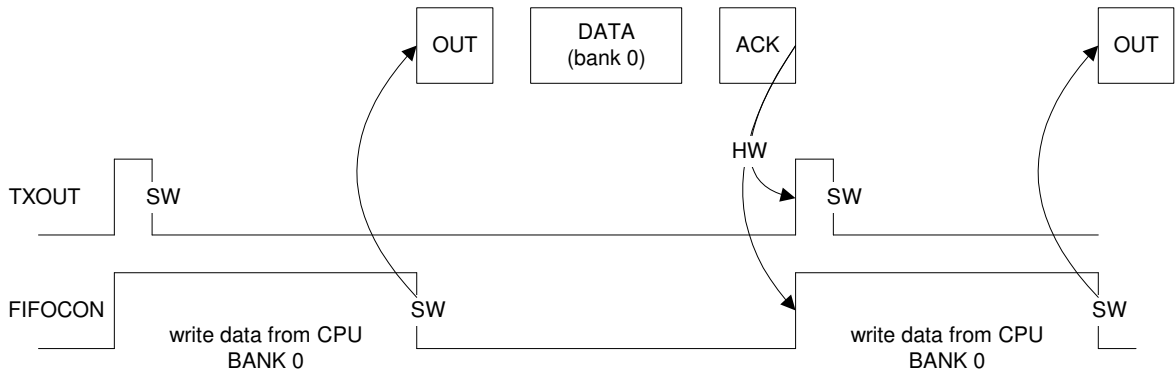

The Pipe must be configured and not frozen first.

Note: if the firmware decides to switch to suspend mode (clear SOFE) even if a bank is ready to be sent, the USB controller will automatically exit from Suspend mode and the bank will be sent.

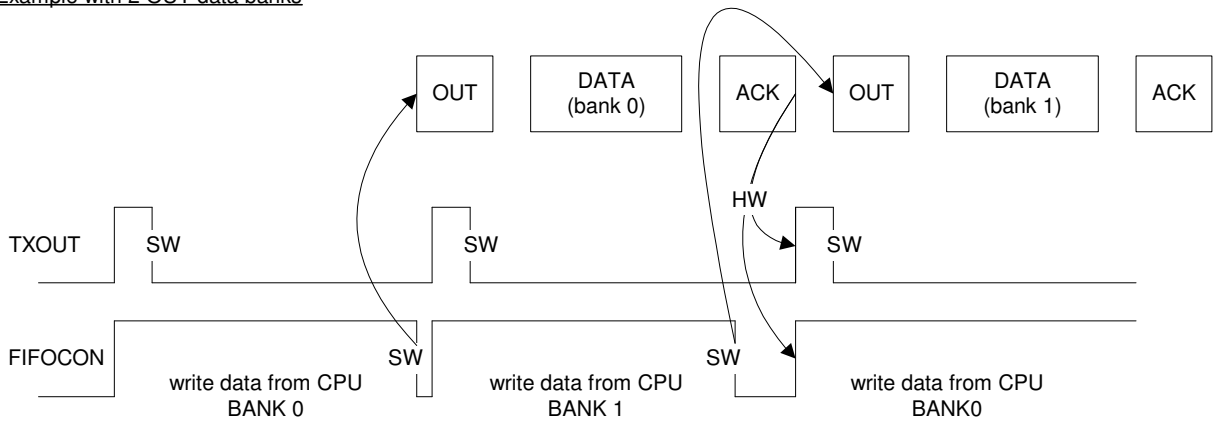

### “Manual” Mode

The TXOUT bit is set by hardware when the current bank becomes free. This triggers an interrupt if the TXOUTE bit is set. The FIFOCON bit is set at the same time. The CPU writes into the FIFO and clears the FIFOCON bit to allow the USB controller to send the data. If the OUT Pipe is composed of multiple banks, this also switches to the next data bank. The TXOUT and FIFOCON bits are automatically updated by hardware regarding the status of the next bank.

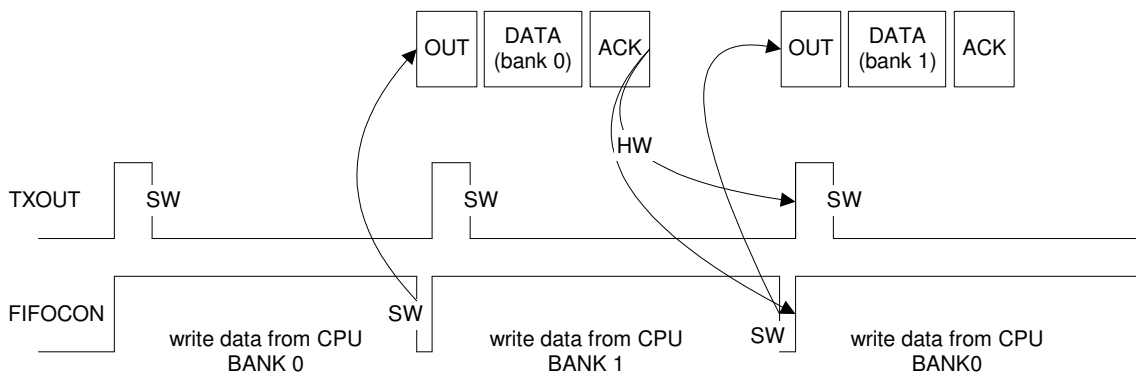

Example with 1 OUT data bank

Example with 2 OUT data banks

Example with 2 OUT data banks

## “Autoswitch” Mode

In this mode, the clear of the FIFOCON bit is performed automatically by hardware each time the Pipe bank is full. The firmware has to check if the next bank is empty or not before writing the next data. On TXOUT interrupt, the firmware fills a complete bank. A new interrupt will be generated each time the current bank becomes free.

## IN Pipe management

The Pipe must be configured first.

## “Manual” Mode

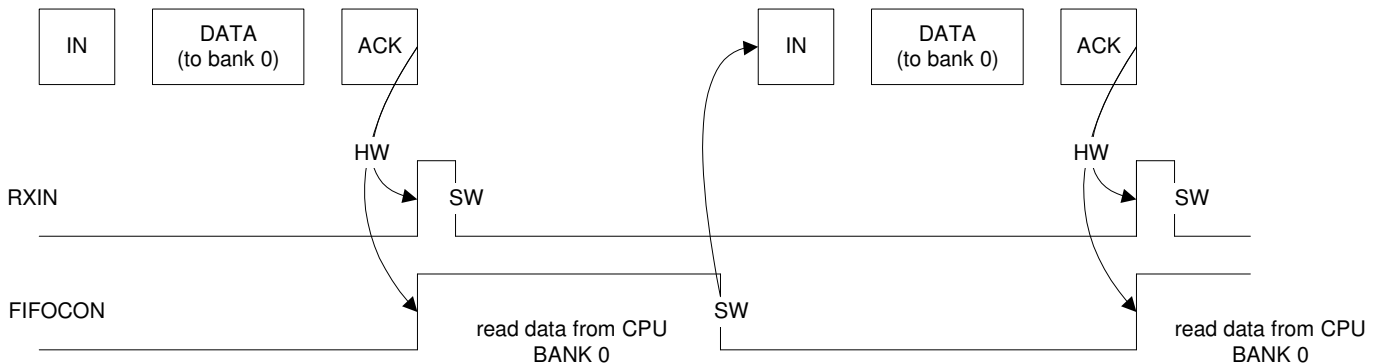

When the Host requires data from the device, the firmware has to determine first the IN mode to use using the INMODE bit:

- INMODE = 0. The INRQX register is taken in account. The Host controller will perform (INRQX+1) IN requests on the selected Pipe before freezing the Pipe. This mode avoids to have extra IN requests on a Pipe.
- INMODE = 1. The USB controller will perform infinite IN request until the firmware freezes the Pipe.

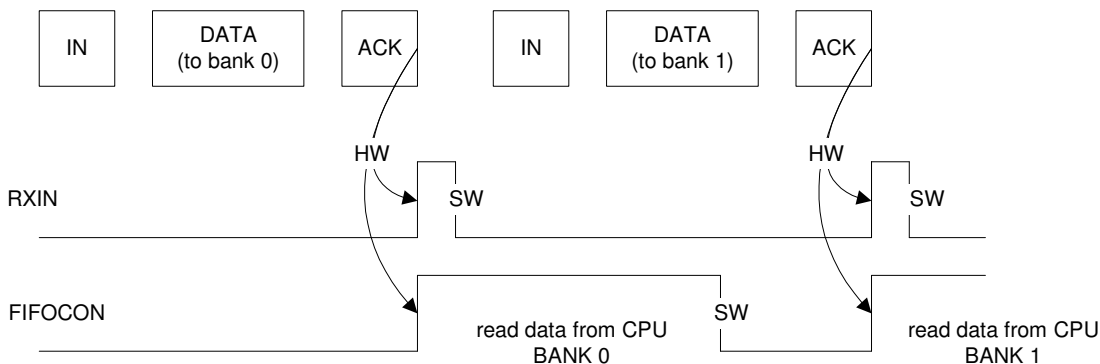

The IN request generation will start when the firmware clear the PFREEZE bit.

Each time the current bank is full, the RXIN and the FIFOCON bits are set. This triggers an interrupt if the RXINE bit is set. The firmware can acknowledge the USB interrupt by clearing the RXIN bit. The Firmware read the data and clear the FIFOCON bit in order to free the current bank. If the IN Pipe is composed of multiple banks, clearing the FIFOCON bit will switch to the next bank. The RXIN and FIFOCON bits are then updated by hardware in accordance with the status of the new bank.

### Example with 1 IN data bank

### Example with 2 IN data banks

**“Autoswitch” Mode**

In this mode, the clear of the FIFOCON bit is performed automatically by hardware each time the Pipe bank is empty. The firmware has to check if the next bank is empty or not before reading the next data. On RXIN interrupt, the firmware reads a complete bank. A new interrupt will be generated each time the current bank contains data to read.

The acknowledge of the RXIN interrupt is always performed by software.

**CRC Error (isochronous only)**

A CRC error can occur during IN stage if the USB controller detects a bad received packet. In this situation, the STALLEDI/CRCERRI interrupt is triggered. This does not prevent the RXINI interrupt from being triggered.

**Interrupt**

Figure 67 shows all the host interrupts sources while Figure 68 details the pipe interrupt sources.

**Figure 67.** USB Host Controller Interrupt System

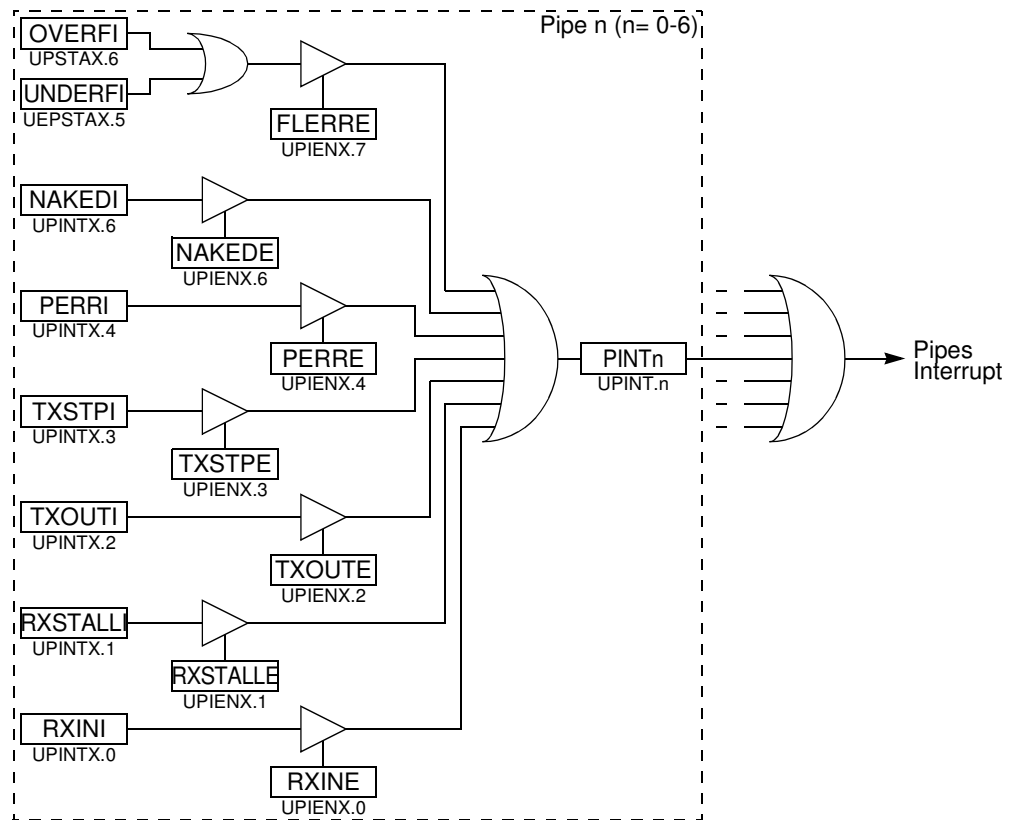

Figure 68. USB Host Controller Pipe Interrupt System

## Registers

### General USB Host Registers

**Table 132.** UHCON Register

UHCON (1.D9h) – USB Host General Control Register

7	6	5	4	3	2	1	0
-	-	-	-	-	RESUME	RESET	SOFE
Bit Number	Bit Mnemonic	Description					
7-3	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
2	RESUME	<b>Send USB Resume</b> Set this bit to generate a USB Resume on the USB bus. Cleared by hardware when the USB Resume has been sent. Clearing by software has no effect.					
1	RESET	<b>Send USB Reset</b> Set this bit to generate a USB Reset on the USB bus. Cleared by hardware when the USB Reset has been sent. Clearing by software has no effect. Refer to the USB reset section for more details.					
0	SOFE	<b>Start Of Frame Generation Enable</b> Set this bit to generate SOF on the USB bus. Clear this bit to disable the SOF generation and to leave the USB bus in Idle state.					

Reset Value = 0000 0000b

**Table 133.** UHINT Register

UHINT (1.D8h) – USB Host General Interrupt Register

7	6	5	4	3	2	1	0
-	HWUP	HSOF	RXRSMI	RSMEDI	RSTI	DDISCI	DCONNI
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
6	HWUP	<b>Host Wake-Up Interrupt</b> Set by hardware when a non-idle state is detected on the USB bus. Shall be clear by software to acknowledge the interrupt. Setting by software has no effect.					
5	HSOFI	<b>Host Start Of Frame Interrupt</b> Set by hardware when a SOF is issued by the Host controller. This triggers a USB interrupt when HSOFE is set. Shall be cleared by software to acknowledge the interrupt. Setting by software has no effect.					

Bit Number	Bit Mnemonic	Description
4	RXRSMI	<b>Upstream Resume Received Interrupt</b> Set by hardware when an Upstream Resume has been received from the Device. Shall be cleared by software. Setting by software has no effect.
3	RSMEDI	<b>Downstream Resume Sent Interrupt</b> Set by hardware when a Downstream Resume has been sent to the Device. Shall be cleared by software. Setting by software has no effect.
2	RSTI	<b>USB Reset Sent Interrupt</b> Set by hardware when a USB Reset has been sent to the Device. Shall be cleared by software. Setting by software has no effect.
1	DDISCI	<b>Device Disconnection Interrupt</b> Set by hardware when the device has been removed from the USB bus. Shall be cleared by software. Setting by software has no effect.
0	DCONNI	<b>Device Connection Interrupt</b> Set by hardware when a new device has been connected to the USB bus. Shall be cleared by software. Setting by software has no effect.

Reset Value = 0000 0000b

**Table 134.** UHIEN Register

UHIEN (1.DAh) – USB Host General Interrupt Enable Register

7	6	5	4	3	2	1	0
-	HWUPE	HSOFE	RXRSMI	RSMEDI	RSTE	DDISCI	DCONNE

Bit Number	Bit Mnemonic	Description
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.
6	HWUPE	<b>Host Wake-Up Interrupt Enable</b> Set this bit to enable HWUP interrupt. Clear this bit to disable HWUP interrupt.
5	HSOFE	<b>Host Start Of frame Interrupt Enable</b> Set this bit to enable HSOF interrupt. Clear this bit to disable HSOF interrupt.
4	RXRSMI	<b>Upstream Resume Received Interrupt Enable</b> Set this bit to enable the RXRSMI interrupt. Clear this bit to disable the RXRSMI interrupt.
3	RSMEDI	<b>Downstream Resume Sent Interrupt Enable</b> Set this bit to enable the RSMEDI interrupt. Clear this bit to disable the RSMEDI interrupt.
2	RSTE	<b>USB Reset Sent Interrupt Enable</b> Set this bit to enable the RSTI interrupt. Clear this bit to disable the RSTI interrupt.
1	DDISCI	<b>Device Disconnection Interrupt Enable</b> Set this bit to enable the DDISCI interrupt. Clear this bit to disable the DDISCI interrupt.

Bit Number	Bit Mnemonic	Description
0	DCONNEN	<b>Device Connection Interrupt Enable</b> Set this bit to enable the DCONNEN interrupt. Clear this bit to disable the DCONNEN interrupt.

Reset Value = 0000 0000b

**Table 135.** UHADDR Register

UHADDR (1.DBh) – USB Host Address Register

7	6	5	4	3	2	1	0
-	HADDR6	HADDR5	HADDR4	HADDR3	HADDR2	HADDR1	HADDR0

Bit Number	Bit Mnemonic	Description
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.
6-0	HADDR6:0	<b>USB Host Address</b> These bits contains the address of the USB Device.

Reset Value = 0000 0000b

**Table 136.** UHFNUMH Register

UHFNUMH (1.DCh) – USB Host Frame Number High Register

7	6	5	4	3	2	1	0
-	-	-	-	-	FNUM10	FNUM9	FNUM8

Bit Number	Bit Mnemonic	Description
7-4	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.
3-0	FNUM10:8	<b>Frame Number</b> The value contained in tis register is the current SOF number. This value can be modified by software.

Reset Value = 0000 0000b

**Table 137.** UHFNUML Register

UHFNUML (1.DDh) – USB Host Frame Number Low Register

7	6	5	4	3	2	1	0
FNUM7	FNUM6	FNUM5	FNUM4	FNUM3	FNUM2	FNUM1	FNUM0
Bit Number	Bit Mnemonic	Description					
7-0	FNUM7:0	<b>Frame Number</b> The value contained in this register is the current SOF number. This value can be modified by software.					

Reset Value = 0000 0000b

Bit Number	Bit Mnemonic	Description					
7-0	FLEN7:0	<b>Frame Length</b> The value contained					

Reset Value = 0000 0000b

## USB Host Pipe Registers

**Table 139.** UPNUM Register

UPNUM (1.C9h) – USB Host Pipe Number Register

7	6	5	4	3	2	1	0
-	-	-	-	-	PNUM2	PNUM1	PNUM0
Bit Number	Bit Mnemonic	Description					
7-3	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
2-0	PNUM2:0	<b>Pipe Number</b> Select the pipe using this register. The USB Host registers ended by a X correspond then to this number. This number is used for the USB controller following the value of the PNUMD bit.					

Reset Value = 0000 0000b

**Table 140.** UPRST Register

UPRST (1.CAh) – USB Host Pipe Reset Register

7	6	5	4	3	2	1	0
-	P6RST	P5RST	P4RST	P3RST	P2RST	P1RST	P0RST
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
6	P6RST	<b>Pipe 6 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 6.					
5	P5RST	<b>Pipe 5 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 5.					
4	P4RST	<b>Pipe 4 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 4.					
3	P3RST	<b>Pipe 3 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 3.					
2	P2RST	<b>Pipe 2 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 2.					
1	P1RST	<b>Pipe 1 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 1.					
0	P0RST	<b>Pipe 0 Reset</b> Set this bit to 1 and reset this bit to 0 to reset the Pipe 0.					

Reset Value = 0000 0000b

**Table 141.** UPCONX Register

UPCONX (1.CBh) – USB Host Pipe Control Register

7	6	5	4	3	2	1	0
-	PFREEZE	INMODE	AUTOSW	RSTDT	PNUM	DFCRDY	PEN
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
6	PFREEZE	<b>Pipe Freeze</b> Set this bit to Freeze the Pipe requests generation. Clear this bit to enable the Pipe request generation. This bit is set by hardware when: - the pipe is not configured - a STALL handshake has been received on this Pipe - An error occurs on the Pipe (PERR = 1) - (INRQ+1) In requests have been processed This bit is set at 1 by hardware after a Pipe reset or a Pipe enable.					

Bit Number	Bit Mnemonic	Description
5	INMODE	<b>IN Request mode</b> Set this bit to allow the USB controller to perform infinite IN requests when the Pipe is not frozen. Clear this bit to perform a pre-defined number of IN requests. This number is stored in the UINRQX register.
4	AUTOSW	<b>Auto Switch Bank</b> Set this bit to allow the auto switch bank mode for this Pipe. Clear this bit to otherwise.
3	RSTDT	<b>Reset Data Toggle</b> Set this bit to reset the Data Toggle to its initial value for the current Pipe. Cleared by hardware when proceed. Clearing by software has no effect.
2	PNUMS	<b>Pipe Number Select Bit</b> Set to configure the PNUM used by the DFC. Clear to configure the PNUM used by the CPU.
1	DFCRDY	<b>DFC Ready Bit</b> Set to resume/enable the DFC interface. Clear to pause the DFC interface.
0	PEN	<b>Pipe Enable</b> Set to enable the Pipe. Clear to disable and reset the Pipe.

Reset Value = 0000 0000b

**Table 142.** UPCFG0X Register

UPCFG0X (1.CCh) – USB Pipe Configuration 0 Register

7	6	5	4	3	2	1	0
PTYPE1	PTYPE0	PTOKEN1	PTOKEN0	PEPNUM3	PEPNUM2	PEPNUM1	PEPNUM0
Bit Number	Bit Mnemonic	Description					
7-6	PTYPE1:0	<b>Pipe Type</b> Select the type of the Pipe: - 00: Control - 01: Isochronous - 10: Bulk - 11: Interrupt					
5-4	PTOKEN1:0	<b>Pipe Token</b> Select the Token to associate to the Pipe: - 00: SETUP - 01: IN - 10: OUT - 11: reserved					
3-0	PEPNUM3:0	<b>Pipe Endpoint Number</b> Set this field according to the Pipe configuration. Set the number of the Endpoint targeted by the Pipe. This value is from 0 and 15.					

Reset Value = 0000 0000b

**Table 143.** UPCFG1X Register

UPCFG1X (1.CDh) – USB Pipe Configuration 1 Register

7	6	5	4	3	2	1	0
-	PSIZE2	PSIZE1	PSIZE0	PBK1	PBK0	ALLOC	-
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
6-4	PSIZE2:0	<b>Pipe Size</b> Select the size of the Pipe: - 000: 8 - 001: 16 - 010: 32 - 011: 64 - 100: 128 - 101: 256 - 110: 512 - 111: 1024					
3-2	PBK1:0	<b>Pipe Bank</b> Select the number of bank to declare for the current Pipe. - 00: 1 bank - 01: 2 banks - 10: invalid - 11: invalid					
1	ALLOC	<b>Configure Pipe Memory</b> Set to configure the pipe memory with the characteristics. Clear to update the memory allocation. Refer to the Memory Management chapter for more details.					
0	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					

Reset Value = 0000 0000b

**Table 144.** UPCFG2X Register

INTFRQ7	INTFRQ6	INTFRQ5	INTFRQ4	INTFRQ3	INTFRQ2	INTFRQ1	INTFRQ0
Bit Number	Bit Mnemonic	Description					
7-0	INTFRQ7:0	<b>Interrupt Pipe Request Frequency</b> These bits are the maximum value in millisecond of the pulling period for an Interrupt Pipe. This value has no effect for a non-Interrupt Pipe.					

Reset Value = 0000 0000b

**Table 145.** UPSTAX Register

UPSTAX (1.CEh) – USB Pipe Status Register

7	6	5	4	3	2	1	0
CFGOK	OVERFI	UNDERFI	-	DTSEQ1	DTSEQ0	NBUSYBK1	NBUSYBK0
Bit Number	Bit Mnemonic	Description					
7	CFGOK	<b>Configure Pipe Memory OK</b> Set by hardware if the required memory configuration has been successfully performed. Cleared by hardware when the pipe is disabled. The USB reset and the reset pipe have no effect on the configuration of the pipe.					
6	OVERFI	<b>Overflow</b> Set by hardware when a the current Pipe has received more data than the maximum length of the current Pipe. An interrupt is triggered if the FLERRE bit is set. Shall be cleared by software. Setting by software has no effect.					
5	UNDERFI	<b>Underflow</b> Set by hardware when a transaction underflow occurs in the current isochronous or interrupt Pipe. The Pipe can't send the data flow required by the device. A ZLP will be sent instead. An interrupt is triggered if the FLERRE bit is set. Shall be cleared by software. Setting by software has no effect. Note: the Host controller has to send a OUT packet, but the bank is empty. A ZLP will be sent and the UNDERFI bit is set underflow for interrupt Pipe:					
4	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
3-2	DTSEQ1:0	<b>Toggle Sequencing Flag</b> Set by hardware to indicate the PID data of the current bank: 00bData0 01bData1 1xbReserved. For OUT Pipe, this value indicates the next data toggle that will be sent. This is not relative to the current bank. For IN Pipe, this value indicates the last data toggle received on the current bank.					
1-0	NBUSYBK1:0	<b>Busy Bank Flag</b> Set by hardware to indicate the number of busy bank. For OUT Pipe, it indicates the number of busy bank(s), filled by the user, ready for OUT transfer. For IN Pipe, it indicates the number of busy bank(s) filled by IN transaction from the Device. 00bAll banks are free 01b1 busy bank 10b2 busy banks 11bReserved.					

Reset Value = 0000 0000b

**Table 146.** UPINRQX Register

UPINRQX (1.DFh) – USB Pipe IN Number Of Request Register

7	6	5	4	3	2	1	0
INRQ7	INRQ6	INRQ5	INRQ4	INRQ3	INRQ2	INRQ1	INRQ0
Bit Number	Bit Mnemonic	Description					
7-0	INRQ7:0	<b>IN Request Number Before Freeze</b> Enter the number of IN transactions before the USB controller freezes the pipe. The USB controller will perform (INRQ+1) IN requests before to freeze the Pipe. This counter is automatically decreased by 1 each time a IN request has been successfully performed.					

Reset Value = 0000 0000b

**Table 147.** UPERRX Register

UPERRX (1.D7h) – USB Pipe Error Register

7	6	5	4	3	2	1	0
-	COUNTER1	COUNTER0	CRC16	TIMEOUT	PID	DATAPID	DATATGL
Bit Number	Bit Mnemonic	Description					
7-6	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.					
5	COUNTER1:0	<b>Error counter</b> This counter is increased by the USB controller each time an error occurs on the Pipe. When this value reaches 3, the Pipe is automatically frozen. Clear these bits by software.					
4	CRC16	<b>CRC16 Error</b> Set by hardware when a CRC16 error has been detected. Shall be cleared by software. Setting by software has no effect.					
3	TIMEOUT	<b>Time-out Error</b> Set by hardware when a time-out error has been detected. Shall be cleared by software. Setting by software has no effect.					
2	PID	<b>PID Error</b> Set by hardware when a PID error has been detected. Shall be cleared by software. Setting by software has no effect.					
1	DATAPID	<b>Data PID Error</b> Set by hardware when a data PID error has been detected. Shall be cleared by software. Setting by software has no effect.					
0	DATATGL	<b>Bad Data Toggle</b> Set by hardware when a data toggle error has been detected. Shall be cleared by software. Setting by software has no effect.					

Reset Value = 0000 0000b

**Table 148.** UPINTX Register

UPINTX (1.C8h) – USB Pipe Interrupt Register

	7	6	5	4	3	2	1	0
	FIFOCON	NAKEDI	RWAL	PERRI	TXSTPI	TXOUTI	RXSTALLI	RXINI

Bit Number	Bit Mnemonic	Description
7	FIFOCON	<p><b>FIFO Control</b></p> <p>For OUT and SETUP Pipe: Set by hardware when the current bank is free, at the same time than TXOUT or TXSTP. Clear to send the FIFO data and to switch the bank. Setting by software has no effect.</p> <p>For IN Pipe: Set by hardware when a new IN message is stored in the current bank, at the same time than RXIN. Clear to free the current bank and to switch to the following bank. Setting by software has no effect.</p>
6	NAKEDI	<p><b>NAK Handshake received</b></p> <p>Set by hardware when a NAK has been received on the current bank of the Pipe. This triggers an interrupt if the NAKEDE bit is set in the UPIENX register. Shall be clear to handshake the interrupt. Setting by software has no effect.</p>
5	RWAL	<p><b>Read/Write Allowed</b></p> <p>OUT Pipe: Set by hardware when the firmware can write a new data into the Pipe FIFO. Cleared by hardware when the current Pipe FIFO is full.</p> <p>IN Pipe: Set by hardware when the firmware can read a new data into the Pipe FIFO. Cleared by hardware when the current Pipe FIFO is empty. This bit is also cleared by hardware when the RXSTALL or the PERR bit is set</p>
4	PERRI	<p><b>PIPE Error</b></p> <p>Set by hardware when an error occurs on the current bank of the Pipe. This triggers an interrupt if the PERRE bit is set in the UPIENX register. Refers to the UPERRX register to determine the source of the error. Automatically cleared by hardware when the error source bit is cleared.</p>
3	TXSTPI	<p><b>SETUP Bank ready</b></p> <p>Set by hardware when the current SETUP bank is free and can be filled. This triggers an interrupt if the TXSTPE bit is set in the UPIENX register. Shall be cleared to handshake the interrupt. Setting by software has no effect.</p>
2	TXOUTI	<p><b>OUT Bank ready</b></p> <p>Set by hardware when the current OUT bank is free and can be filled. This triggers an interrupt if the TXOUTE bit is set in the UPIENX register. Shall be cleared to handshake the interrupt. Setting by software has no effect.</p>
1	RXSTALLI / CRCERR	<p><b>STALL Received / Isochronous CRC Error</b></p> <p>Set by hardware when a STALL handshake has been received on the current bank of the Pipe. The Pipe is automatically frozen. This triggers an interrupt if the RXSTALLE bit is set in the UPIENX register. Shall be cleared to handshake the interrupt. Setting by software has no effect.</p> <p>For Isochronous Pipe: Set by hardware when a CRC error occurs on the current bank of the Pipe. This triggers an interrupt if the TXSTPE bit is set in the UPIENX register. Shall be cleared to handshake the interrupt. Setting by software has no effect.</p>

Bit Number	Bit Mnemonic	Description
0	RXINI	<b>IN Data received</b> Set by hardware when a new USB message is stored in the current bank of the Pipe. This triggers an interrupt if the RXINE bit is set in the UPIENX register. Shall be cleared to handshake the interrupt. Setting by software has no effect.

Reset Value = 0000 0000b

PBYCT7	PBYCT6	PBYCT5	PBYCT4	PBYCT3	PBYCT2	PBYCT1	PBYCT0

Bit Number	Bit Mnemonic	Description
7-0	PBYCT7:0	<b>Byte Count (low) Bits</b> Set by the hardware. PBYCT10:0 is: - (for OUT Pipe) increased after each writing into the Pipe and decremented after each byte sent, - (for IN Pipe) increased after each byte received by the host, and decremented after each byte read by the software.

Reset Value = 0000 0000b

**Table 153.** UPINT Register

UPINT (1.D6h) – USB Pipe IN Number Of Request Register

	<b>7</b>	<b>6</b>	<b>5</b>	<b>4</b>	<b>3</b>	<b>2</b>	<b>1</b>	<b>0</b>
	-	PINT6	PINT5	PINT4	PINT3	PINT2	PINT1	PINT0
	<b>Bit Number</b>	<b>Bit Mnemonic</b>	<b>Description</b>					
	7	-	<b>Reserved</b> The value read from this bit is always 0. Do not set this bit.					
	6-0	PINT6:0	<b>Pipe Interrupts Bits</b> Set by hardware when an interrupt is triggered by the UPINTX register and if the corresponding endpoint interrupt enable bit is set. Cleared by hardware when the interrupt source is served.					

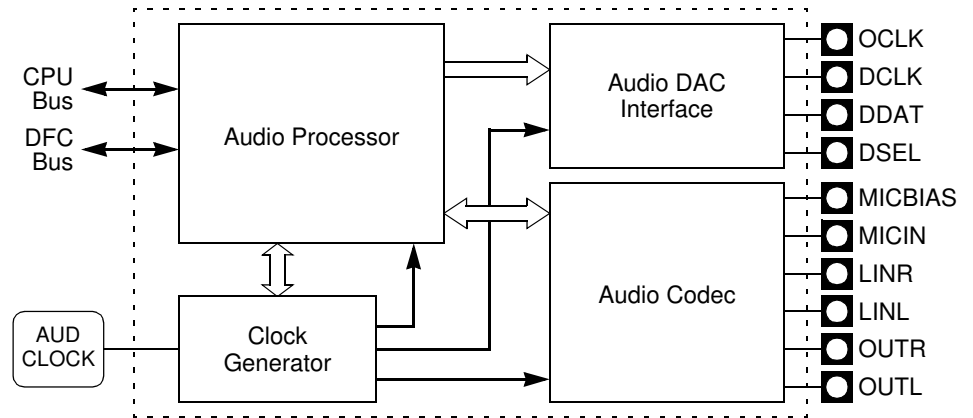

Reset Value = 0000 0000b

## Audio Controller

The Audio Controller implemented in AT85C51SND3B derivatives is based on four functional blocks detailed in the following sections:

- The Clock Generator
- The Audio Processor
- The Audio Codec
- The Audio DAC Interface

**Figure 69.** Audio Controller Block Diagram

## Clock Generator

The clock generator generates the audio controller clocks based on the audio clock issued by the clock controller as detailed in Section “System Clock Generator”, page 30. As shown in Figure 70, it contains an Audio Frequencies Generator able to generate the audio sampling and over-sampling frequencies fed by a normalized clock. This generator is based on a PLL and is entirely controlled by the audio processor depending on the encoded or decoded audio stream characteristics.

**Figure 70.** Audio Controller Clock Generator

## Audio Processor

The audio processor is based on three functional blocks as shown in Figure 71.

- The Audio Buffer
- The Digital Audio Processor
- The Baseband Processor

**Figure 71.** Audio Processor Block Diagram

**Audio Buffer**

The audio buffer receives the audio data flow coming from DFC or the C51. It is based on 1 Kbyte of dual-port RAM.

*Buffer Description*

The audio buffer can be accessed in read or write mode by both C51 and DFC. Access selection is done by the ABACC bit in APCON1. Considering the DFC, two channels can be established at the same time one in which the audio processor is the source and one in which the audio processor is the destination. To achieve such scheme, the audio buffer can be configured using ABSPLIT in APCON1 as one (see Figure 72a) or two (see Figure 72b) buffers, each containing two data packets of 512 or 256 bytes size.

**Figure 72.** Audio Buffer Configuration

Internal read or write pointers can be reset at any time by setting respectively ABRPR and ABWPR bits in APCON1. These bits are automatically reset by hardware.

*Buffer Management*

The C51 reads from or writes to the buffer through the APDAT register. Management is controlled by a couple of flags informing the user that data can be written to the buffer or read from the buffer depending on the current operation.

In case of write (audio stream decoding or codec firmware update) APREQI flag in APINT is set every time a data packet (256 or 512 bytes) can be written to the buffer i.e. buffer empty or half full. APREQI is cleared when the buffer becomes full.

In case of read (audio stream encoding) APRDYI flag in APINT is set every time a data packet (256 or 512 bytes) can be retrieved from the buffer i.e. buffer full or half full. APRDYI is cleared when the buffer becomes empty.

These flags can generate an interrupt when APREQE bit and APRDYE bit in APIEN are respectively set (see Section "Interrupts").

In order to avoid any spurious interrupts on the CPU side when a data transfer with the data flow controller is established, APREQE and APRDYE must be left cleared.

## **Digital Audio Processor**

The digital audio processor is based on a proprietary digital signal processor. It provides capability to decode many digital audio formats like MP3, WMA, G726, RAW PCM... and to encode some digital audio formats like G726, RAW PCM...

### *Processor Initialization*

Prior to enable the digital audio processor by setting the DAPEN bit in APCON1<sup>(1)</sup>, the C51 must load the processor codec firmware which is the stream decoder or encoder. This can be achieved by setting APLOAD<sup>(2)</sup> bit in APCON1 and loading data using the C51 (through APDAT) or the DFC as detailed in the Section "Audio Buffer". As soon as the codec firmware is fully loaded, the digital audio processor can be enabled with the effect to start the codec execution. Then the audio stream type that can be decoded or encoded depends on the codec firmware loaded.

Note:    1. Clearing DAPEN bit resets the code writing pointer address to 0000h.  
          2. Toggling APLOAD bit leaves the code writing pointer address unchanged.

### *Processor Interface*

The C51 interfacing the processor through 3 registers: APCON0 by using APCMD6:0 bits, APSTA and APINT by using APEVTI bit. APCMD field is used to send commands to the processor while APSTA and APEVTI are used by the processor to trigger an event or give a status to the C51. Command and status relies on the processor codec firmware and are beyond the scope of this document.

### *Play Time*

In order to allow time stamping in case of synchronized lyrics (karaoke mode), a 24-bit time stamp is provided by APTIM2:0 registers with APTIM2 being the MSB and APTIM0 being the LSB. Time unit is millisecond.

Getting the time value is done by reading first APTIM0, then APTIM1 and APTIM2. The counter value is latched during read sequence, avoiding bad reading if increment occurs.

Initializing the time value is done by writing first APTIM0, then APTIM1 and APTIM2. The counter is updated after writing last time stamp byte APTIM2.

Time value is automatically updated by the audio processor in case of fast forward/rewind operating mode. Time value is reset when operating mode switches from Stop to Play mode and frozen when in Pause mode.

### *Audio Stream Interface*

Every codec firmwares (decoder or encoder) share a set of registers allowing to perform configuration and control and to get status from the decoding or encoding process. This set of registers is composed of ASCON, the audio stream control register and ASSTA0 ASSTA1 and ASSTA2, the audio stream status registers. The content of these registers depends on the codec firmware loaded and are beyond the scope of this document.

## **Baseband Processor**

Several digital baseband treatments can be applied to the digital audio signal immediately before internal or external D/A conversion:

- Digital volume control
- 3-bands equalizer
- Bass boost effect
- Virtual surround effect
- Mixing mode

The baseband processor is enabled by setting BPEN bit in AUCON. When disabled (BPEN bit cleared) all of the above treatments are disabled.

### Digital Volume Control

The digital volume is controlled separately on right and left channel by setting the DVR4:0 and DVL4:0 bits respectively in APRDVOL and APLDVOL according to Table 154.

**Table 154.** Digital Volume Control Gain

DVx4:0	Gain Value	DVx4:0	Gain Value	DVx4:0	Gain Value
00000	+6 dB	01011	-16dB	10110	-38 dB
00001	+4 dB	01100	-18 dB	10111	-40 dB
00010	+2 dB	01101	-20 dB	11000	-42 dB
00011	+0 dB	01110	-22 dB	11001	-44 dB
00100	-2 dB	01111	-24 dB	11010	-46 dB
00101	-4 dB	10000	-26 dB	11011	-48 dB
00110	-6 dB	10001	-28 dB	11100	-50 dB
00111	-8 dB	10010	-30 dB	11101	-52 dB
01000	-10 dB	10011	-32 dB	11110	-54 dB
01001	-12 dB	10100	-34 dB	11111	Mute <sup>(1)</sup>
01010	-14 dB	10101	-36 dB		

Note: 1. When DVR4:0 and DVL4:0 are set to mute, audio processor is still sending data to the audio codec or the audio interface with data set to the corresponding 0 value.

### Equalizer Volume Control

A 3-band equalizer control is provided for tone adjustment or predefined tone shapes like classic, jazz, rock...

The equalizer gain is controlled in each band by programming DVB4:0 in APBDVOL for the bass band, DVM4:0 in APMDVOL for the medium band and DVT4:0 in APTDVOL for the treble band according to Table 154. Cut frequencies are defined in Table 155. In order to optimize the power consumption, the 3-band equalizer can be disabled by setting EQU DIS in AUCON. In this case the band gain control is saved but no filtering is applied.

**Table 155.** Equalizer Band Frequency

Band	Frequencies
Bass	F < 750 Hz
Medium	750 Hz < F < 3300 Hz
Treble	F > 3300 Hz

### Bass Boost Effect

A bass boost effect can be established by setting BBOOST bit in AUCON. It consists in a gain increase of +6 dB in the frequency range under 200 Hz.

### Virtual surround Effect

A virtual surround effect can be established by setting VSURND bit in AUCON. It consists in applying a spatial effect to sound on both right and left channels.

### Equalizer Bar-Graph

An 8-band bar-graph equalizer allows dynamic audio volume report inside 8 frequency bands. To read the level of each band, first select the band by setting the EQBS2:0 bits in APEBS from 000b (lowest frequency band) to 111b (highest frequency band) then get the 5-bit band level by reading EQLEV4:0 bits in APELEV.

*Mixing Mode*

A mixing mode can be established by setting MIXEN bit in AUCON. It consists in mixing the ADC output coming from microphone or line-in inputs with the output coming from the audio processor before feeding the internal or external audio DAC.

*Signal Clipping*

When volume controls (global + equalizer + bass boost) leads to signal saturation, output signal is clipped and ACLIPI flag is set in APINT. In such case, strategy to reduce volume is under user's firmware responsibility. ACLIPI flag can generate an interrupt by setting ACLIPE bit in APIEN.

**Interrupts**

As shown in Figure 73, the audio processor interrupt request is generated by 8 different sources: the APREQI, APRDYI, ACLIPI and APGPI4:0 flags in APINT. Both sources can be enabled separately by using the APREQE, APRDYE, ACLIPE and APGPE4:0 bits in APIEN. A global enable of the audio processor interrupt is provided by setting the EAUP bit in IEN0 register. The interrupt is requested each time one of the sources is asserted.

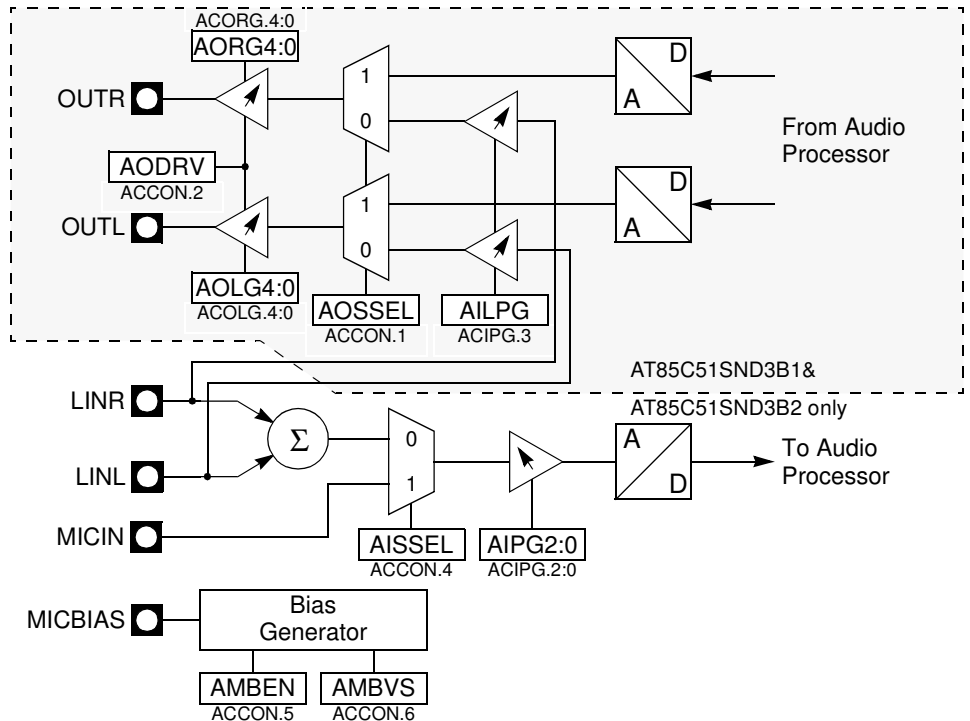

**Figure 73.** Audio Processor Interrupt System

## Audio Codec

The audio codec is controlled by four registers as detailed in Figure 74:

**Figure 74.** Audio Codec Block Diagram

### Audio Outputs AT85C51SND3B1 & AT85C51SND3B2

The audio output system of AT85C51SND3B1 & AT85C51SND3B2 is based on a pair of sigma-delta D/A converter used to convert the audio data with high linearity and high S/N. It is enabled by setting the AOEN bit in ACCON (see Table 178). Audio input system features are detailed in the following sections.

### Anti-Pop Circuitry

In order to avoid any noise when enabling the audio output system an anti-pop circuitry has been implemented on the audio outputs (OUTR and OUTL). It consists in a discharge circuit controlled by AODIS bit in ACAUX (see Table 179) and a preload circuit controlled by AOPRE bit in ACAUX. Prior to enable the audio output system, user must take care to discharge then charge the audio outputs.

### Output Sources

The audio output source can come from either the audio processor or the stereo lines Inputs sources. The selection of the source is done by setting or clearing the AOSEL bit in ACCON according to Table 156.

**Table 156.** Audio Codec Output Source Selection

AOSEL	Selection
0	Line Input (stereo)
1	Audio Processor (mono or stereo) <sup>(1)</sup>

Note: 1. Stereo or mono choice is done by the audio processor depending on the audio flow under decoding.

### Output Gain Control

Analog volume is controlled separately on both channel by setting the AORG.4:0 bits in ACORG for the right channel and the AOLG.4:0 bits in ACOLG for the left channel. Table 157 shows the gain value versus the programmed AORG or AOLG value.

**Table 157.** Audio Codec Output Gain

AORG4:0 AOLG4:0	Gain Value	AORG4:0 AOLG4:0	Gain Value	AORG4:0 AOLG4:0	Gain Value
00000	6 dB	00111	-8 dB	01110	-22 dB
00001	4 dB	01000	-10 dB	01111	-24 dB
00010	2 dB	01001	-12 dB	10000	-26 dB
00011	0 dB	01010	-14 dB	10001	-28 dB
00100	-2 dB	01011	-16 dB	10010	-30 dB
00101	-4 dB	01100	-18 dB	≥ 10011	Mute
00110	-6 dB	01101	-20 dB		

### Output Drive Control

Output buffers can operate in two modes depending on the power supply voltage. These are low impedance or high impedance modes. The low impedance mode is only available in high power supply configuration and allows to drive a typical 32 Ω stereo headphone, while the high impedance mode is available in low or high voltage power supply configurations and allows to drive a typical 50 KΩ stereo amplifier. Control is done by setting or clearing AODRV bit in ACCON according to Table 158.

**Table 158.** Audio Codec Output Drive Selection

AODRV	Drive Selection
0	Low/high voltage 50 KΩ drive
1	High voltage 32 Ω drive

### Audio Inputs

The audio input system is based on a single sigma-delta A/D converter provided for mono recording. It is enabled by setting the AIEN bit in ACCON. Audio input system features are detailed in the following sections.

### Inputs Sources

The audio input source can come from either an electret type microphone input or the stereo lines inputs sources. The selection of the source is done by setting or clearing the AISSEL bit in ACCON according to Table 159. When line inputs are selected as audio input source, stereo channels are combined together in a mono signal prior to feed the preamplifier.

**Table 159.** Audio Codec Input Source Selection

AISSEL	Selection
0	Line Inputs
1	Microphone Input

### Audio Input Preamplifier Gain

The signals coming from audio inputs goes through a preamplifier to adapt levels prior to feed the A/D converter. The preamplifier gain is controlled by AIPG2:0 bits in ACIPG according to Table 160.

**Table 160.** Audio Codec Input Preamplifier Gain

AIPG2:0	Gain Value	AIPG2:0	Gain Value	AIPG2:0	Gain Value
000	0 dB	010	+12 dB	100	+24 dB

AIPG2:0	Gain Value	AIPG2:0	Gain Value	AIPG2:0	Gain Value
001	+6 dB	011	+18 dB	≥ 101	Reserved

### Line Inputs Preamplifier Gain

In AT85C51SND3B1 & AT85C51SND3B2, when Line Inputs are selected as output source (e.g. FM decoder playback) two preamplifier gain values can be applied by setting or clearing AILPG bit in ACIPG according to Table 161.

**Table 161.** Audio Codec Line Inputs Preamplifier Gain

AILPG	Gain Value
0	+6 dB
1	+12 dB

### Microphone Bias

In addition, voltage supply function for an electret type microphone is integrated delivering High bias (1.5V) or low bias (2v) voltage. The high bias voltage output is only available in high power supply configuration, while the low bias voltage output is available in low or high voltage power supply configurations. Bias voltage output is selected by AMBSEL bit in ACCON according to Table 163 and is enabled by AMBEN bit in ACCON according to Table 162.

**Table 162.** Audio Codec Microphone Bias Control

AMBEN	Control
0	Microphone bias output disabled
1	Microphone bias output enabled

**Table 163.** Audio Codec Microphone Bias Voltage Selection

AMBSEL	Voltage Selection
0	high bias voltage 2V output
1	Low bias voltage 1.5 V output

### Audio DAC Interface

The C51 core interfaces to the audio DAC interface through two special function registers: ADICON0 and ADICON1, the Audio DAC Interface Control registers (see Table 183 and Table 184).

Figure 75 shows the audio interface block diagram where blocks are detailed in the following sections.

Figure 75. Audio DAC Interface Block Diagram

**Clock Controller**

As soon as audio DAC interface is enabled by setting ADIEN bit in ADICON0, the master clock generated by the clock generator (see Section “Clock Generator”) is output on the OCLK pin which is the DAC over-sampling clock. The over-sampling ratio is defined by OVERS1:0 bits in ADICON0 according to Table 164 and is selected depending on the DAC capabilities.

Table 164. Audio DAC Interface Over-sampling Ratio

OVERS1:0	Over-sampling Ratio
00	Reserved
01	$128 \cdot F_S$
10	$256 \cdot F_S$
11	$384 \cdot F_S$

For DAC compatibility, the bit clock frequency is programmable for outputting 16 bits or 32 bits per channel using the DSIZE bit in ADICON0 (see Section "Data Converter", page 157), and the word selection signal (DSEL) is programmable for outputting left channel on low or high level according to CSPOL bit in ADICON0 as shown in Figure 76.

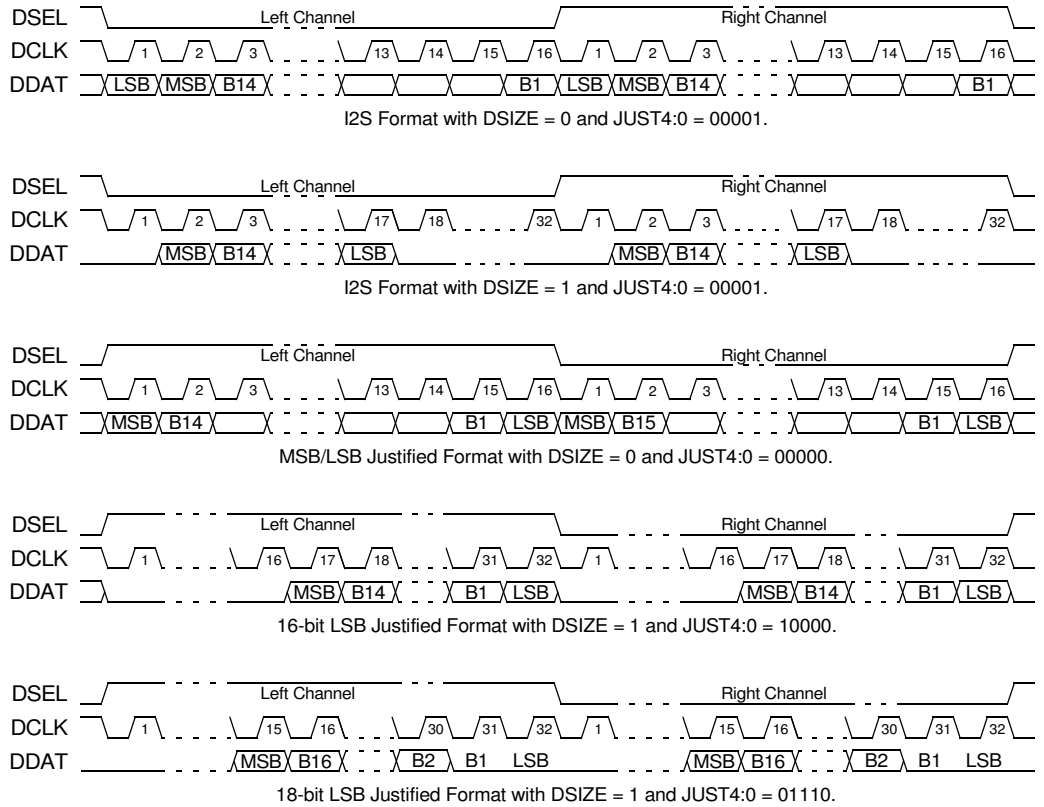

Figure 76. DSEL Output Polarity

**Data Converter**

The data converter block converts the audio stream coming from the audio processor to a serial format. For accepting all PCM formats and I<sup>2</sup>S format, JUST4:0 bits in ADICON1 register are used to shift the data output point. As shown in Figure 77, these bits allow MSB justification by setting JUST4:0 = 00000, LSB justification by setting JUST4:0 = 10000, I<sup>2</sup>S Justification by setting JUST4:0 = 00001, and more than 16-bit LSB justification by filling the low significant bits with logic 0.

**Figure 77. Audio Output Format**

## Registers

## Nand Flash Controller

The AT85C51SND3B derivatives implement a hardware Nand Flash Controller (NFC) embedding the following features:

- Up to 4 Nand Flash (NF) memories
- SMC/XD support with up to 3 NF memories
- 512-byte, 1024-byte, 2048-byte page size support (provision for up to 8192-byte page size)
- Hardware ECC support
- High speed: up to 35 ns cycle time NF support
- Two separated secured memory segments:
  - application segment for user codes, audio codec codes, fonts, screens...
  - mass storage segment for FAT formatting
- Hardware write protection management for application code segment
- Very high data transfer rate in read and write using DFC interface
- Proprietary wear-levelling support with extremely reduced CPU load

## Functional overview

As shown in Figure 78 the NFC architecture is based on six hardware units:

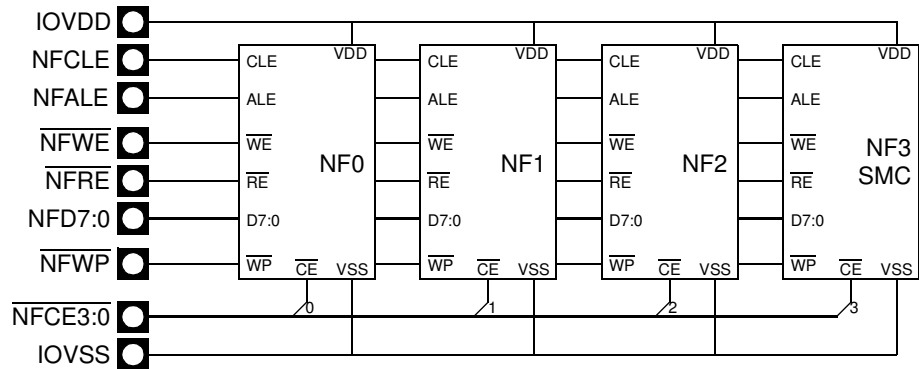

- The Clock unit
- The Control unit
- The Data unit
- The Security unit
- The Card Unit
- The Interrupt unit

These units are detailed in the following sections.

**Figure 78.** NFC Controller Block Diagram

**Figure 79.** Nand Flash Connection

### Clock Unit

The NFC clock is generated based on the clock generator as detailed in Section "DFC/NFC Clock Generator", page 31. As soon as NFEN bit in NFCON is set, the NFC controller receives its system clock and can then be configured.

### Control Unit

The Control unit configures the NFC and gives the user all the flexibility to interface the NF devices. All the flash commands must be produced by the software, and the NFC just sends to the Flash basic operations such as "read Id", "write a byte", "erase a block", ...

### Configuration Descriptor

Prior to any operation, the NFC must be configured with static information concerning the NF devices connected to the product as well as other important information relevant to the desired behavior. The configuration is done by writing a descriptor byte by byte in the NFCFG register. The NF descriptor is composed of eight bytes (detailed in Table 189). The first byte written is byte 0.

After writing a descriptor, a new one can be written to the NFC.

**Table 189.** Configuration Descriptor Content

Byte Offset	Byte Mnemonic	Description
0	NFPGCFG	<b>NF Device Page Configuration Register</b> Refer to Table 190 for register content organization.
1	SMPGCFG	<b>SMC Device Page Configuration Register</b> Refer to Table 190 for register content organization.
2	SCFG1	<b>Sub Configuration Register 1</b> Refer to Table 191 for register content organization.
3	SCFG2	<b>Sub Configuration Register 2</b> Refer to Table 192 for register content organization.
4	FPBH	<b>NF Device First Protected Block Address Registers</b> First address block of protected area. Refer to Section "Write Protection" for detailed information. Reset Value is 0000 0000b, 0000 0000b.
5	FPBL	
6	LPBH	<b>NF Device Last Protected Block Address Registers</b> First address block of protected area. Refer to Section "Write Protection" for detailed information. Reset Value is 0000 0000b, 0000 0000b.
7	LPBL

-	-	-	-	-	-	BSIZE1	BSIZE0

Bit Number	Bit Mnemonic	Description
7-2	-	<b>Reserved</b> The value read from these bits is always 0. Do not set these bits.

Bit Number	Bit Mnemonic	Description
1-0	BSIZE1:0	<b>Block Size Bits</b> Write following value to specify the number of pages per block. This information is needed by the controller for the block protection management. 0 0: 32 pages per block 0 1: 64 pages per block 1 0: 128 pages per block 1 1: 256 pages per block

Reset Value = 0000 0000b

### Specific Action

As soon as the NFC is configured, the NFC is 'idle', i.e. ready for operation and its running status flag NFRUN in NFSTA is cleared. The controller is ready to accept events, typically to prepare a page for read or write.

As long as the NFC remains in the running state (NFRUN flag set), any attempt to new event will lead to an ILLEGAL interrupt.

Here is the list of the possible events:

Writing in the NFACT register as detailed in Table 193 launches a specific action:

- select a device,
- begin a read data transfer (thus the spare zone will be checked),
- begin a write data transfer (thus the spare zone will be set),
- stop a data transfer before the end of a page,
- force CE low.

**Table 193.** Action Decoding

EXT1:0		ACT2:0			Launched Action
x	x	0	0	0	No action
DEV		0	0	1	Device selection. The device number is selected by EXT.
x	x	0	1	0	Read session.
x	x	0	1	1	Write session.
x	CELOW	1	0	0	Selected $\overline{\text{NFCE}}$ signal assertion.
x	x	1	0	1	Data transfer stop.
A9	A8	1	1	0	Column address extension.
x	x	1	1	1	Reserved for future use.

### Device Selection

This command selects the device which will receive the next incoming events. The device number is memorized until a new device selection action is performed.

DEV is the device number. SMC shall always be connected on device 3. Table 194 summarizes the possible configurations: if DEV is a device that does not comply with the configuration allowed, an illegal interrupt is triggered.

**Table 194.** Device Selection Allowed Configuration

SMCEN	NUMDEV	Allowed DEV	Comment
0	0	0	
	1	0, 1	
	2	0, 1, 2	
	3	0, 1, 2, 3	
1	0	3 (SMC)	No NF memory is selected
	1	3 (SMC), 0	
	2	3 (SMC), 0, 1	The $\overline{\text{SMLCK}}$ signal can not be used in this configuration, the SMLCK bit is irrelevant.
	3	3 (SMC), 0, 1, 2	Neither $\overline{\text{SMLCK}}$ nor $\overline{\text{SMINS}}$ signals can be used in this configuration. SMCD and SMLCK bits have an irrelevant value. SMCTE shall be cleared.

*“Read” Session*

A “read” session is launched and the DFC flow control is enabled. When processing the spare zone, its information will be checked.

*“Write” Session*

A “write” session is launched and the DFC flow control is enabled. When processing the spare zone, its information will be set.

*$\overline{\text{NFCE}}$  Signal Force Low*

The 512B-pages memories need to keep asserted the  $\overline{\text{NFCE}}$  line during the access time of a data. This can be done by setting the CELOW bit. In this case, the  $\overline{\text{NFCEx}}$  signal selected by the last ‘device select’ action is asserted ( $\text{NFCE}[\text{DEV}] = \text{L}$ ).

If a new ‘device select’ action occurs while the CELOW bit is set, the  $\overline{\text{NFCEx}}$  signal of the old selected device is de-asserted ( $\text{NFCE}[\text{OLD\_DEV}] = \text{H}$ ), and the  $\overline{\text{NFCEx}}$  signal of the new one is asserted ( $\text{NFCE}[\text{NEW\_DEV}] = \text{L}$ ).

Clearing the CELOW bit does not force the  $\overline{\text{NFCE}}$  signal high:

- The  $\overline{\text{NFCE}}$  signal is automatically asserted at the beginning of the execution of any new commands.
- The  $\overline{\text{NFCE}}$  signal is automatically de-asserted at the completion of the commands.

*Data Transfer Stop*

This action stops the NFC when the data transfer is finished. In this case, the controller state becomes “not running” (NFRUN bit cleared). This can also be used as an abort signal in streaming mode.

*Column Address Extension*

The 512B-pages memories have different kind of read commands (00h, 01h, 50h) depending the data zone that need to be processed (1st half, 2nd half or spare). The column address given is relative to the zone chosen by the read command. The NFC needs to have the absolute column address to stop automatically at the end of the page. The column address extension is given thanks to that command. A9:8 holds the address extension.

- 00h selects the 1st half zone, i.e. the 0-255 range in the data zone. This is the default value. A read or a write in NFADC resets A9:8 to 00h.
- 01h selects the 2nd half zone, i.e. the 256-511 range in the data zone.
- 10h selects the spare zone, i.e. the 512-527 range in the data zone.

Note that it is not possible to reset A9:8 after each command (write in NFCMD): the device status read command is used after opening a page (for read) to poll the busy status.

### Command Sending

Writing a command in NFCMD generates the following cycles:

Assembly code: `mov direct, #`

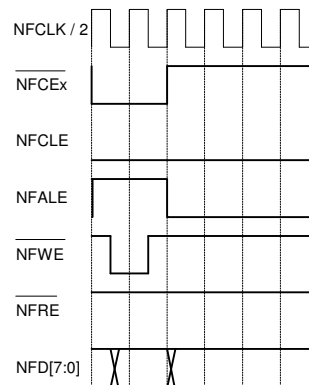

Command

A write in that register re-initializes the ECC engine and the ECC FIFO. A read in that register returns an unexpected value.

### Address Sending

Writing an address in NFADC (column address) or NFADR (row address) generates the following cycles:

Assembly code: `mov direct, #`

Address

The NFADC register is used to select the column address. The NFC uses that information to build an internal byte counter in the page, thus allowing it to stop at the end of the page. 512B NF memories (NDB= 1) have 1 column cycle. Other NF memories have 2 column cycles.

The NFADR register is used to select the raw address, i.e. the page address. The NFC uses that information to verify if the block is protected or not.

Both kind of information are reset after a read of a write of the NFCMD register. A read in NFADC or NFADR returns an unexpected value.

## Data Reading/Writing

The NFDAT and NFDATF registers allow reading or writing of a byte without the use of the DFC as detailed in the Section “Data Unit”. It launches an immediate read or write NF cycle, depending if the software reads or writes in those registers.

Note: The ECC is also computed when byte are read or written via NFDAT or NFDATF.

- A write in NFDAT or NFDATF will produce an immediate “write cycle” (the NF signals will be asserted accordingly) to store the byte given by the CPU.

Assembly code: `mov direct, #`

Write data

- A read of NFDATF or NFADC returns to the CPU the byte contained in that register and launches in background a new “read cycle” (the NF signals will be asserted accordingly). Once the “read cycle” is completed, the byte is held in the NFDAT and NFDATF or NFADC registers. (*The NFC stays in the running state (NFRUN set) as long as the “read cycle” is not performed.*)

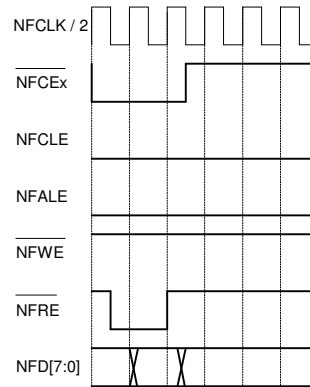

Note: The NFADC register is particularly suitable to read and poll the nand flash(es) status register.

Depending on the Nand Flash manufacturer, read cycle waveform may differ on the NFRE pulse width parameter. In order to be compliant with all memories, NFRE read pulse width can be programmed using TRS bit in NFCON according to Table 195.

**Table 195.** Read Cycle Configuration

TRS	Description
0	<b>[1.5; 0.5] Cycle</b> NFRE asserted during 1.5 clock period and deasserted during 0.5 clock period.
1	<b>[1.0;1.0] Cycle</b> NFRE asserted during 1 clock period and deasserted during 1 clock period.

Assembly code: `mov #, direct`

Read data, TRS cleared  
CPU: 40 ns setup, timing [1.5; 0.5]  
[15;30] ns hold

Read data, TRS set  
CPU: 40 ns setup Timing [1; 1]  
[15;30] ns hold

- A read of NFDAT returns to the CPU the byte contained in that register, but does not launch an extra background “read cycle”.

Assembly code: `mov #, direct`

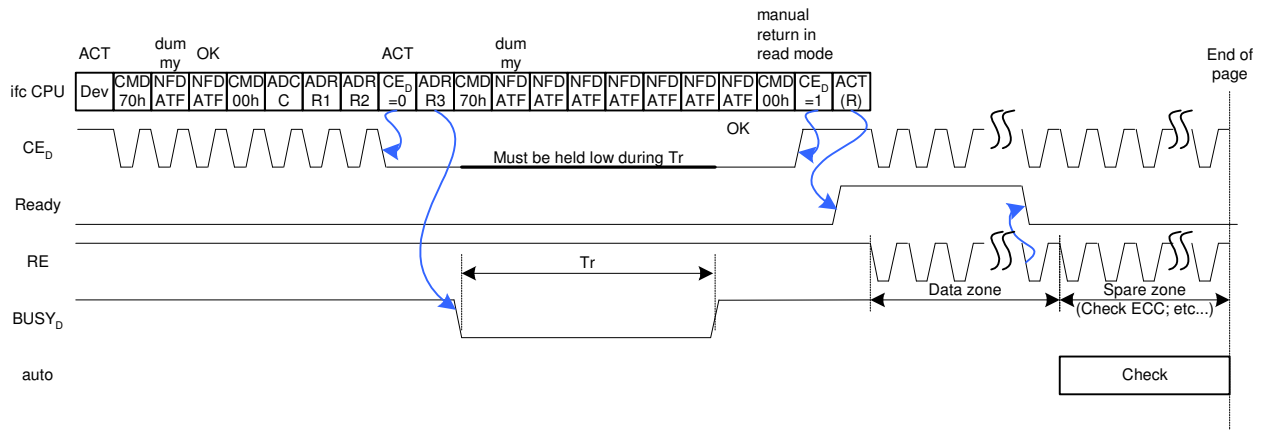

In all the previous examples, the  $\overline{\text{NFCE}}$  line is asserted low and de-asserted at the end of the cycle. This allows minimizing the power consumption.

### Access Example

Figure 80 shows a read access in a 512B page. Note that the  $\overline{\text{NFCE}}$  must be held low during the access time for that kind of memory:

Figure 80. Nand Flash Read Example

Legend:

- “ifc CPU” illustrates the commands given by the CPU to the NFC.
- “auto” illustrates the actions automatically launched by the NFC.
- “ready” is the flow control line between the DFC macro and the NFC interface.
- “BUSY<sub>D</sub>” is the busy state of the device D.
- “P” is the Polling action.

Data Unit

The Data Unit works closely to the DFC and is responsible of all the data transfer between the NF memories and on-chip memories (USB, SRAM, ...).

Data and Spare Zone

For management convenience, the controller is mapping a memory page as some data and spare zones.

A ‘data zone’ is a data area composed of NDB contiguous bytes.

The ‘spare zone’ is located after the ‘data zone’ until the end of the page.

NDB is part of the configuration descriptor (see Table 190) and its use is described in the following examples:

- SMC page, “512B” NF page, “512B” XD card  
A page is composed of 512 contiguous data bytes (NDB= 1), followed by a spare zone of 16 bytes.

- “2kB” NF page  
A page is composed of 1024 contiguous data bytes (NDB= 4), followed by a spare zone of 64 bytes.

Spare Zone Content

The “16-byte” spare zone contains information as specified in Table 196.

**Table 196. Spare Zone Content**

Offset	Description
0-1	User Data Area. Shall be managed by software.
2	ECC Valid. Managed by NFC.
3	User Data Byte. Managed by NFC through NFUDAT register.
4	Data Status Flag. Shall be managed by software.
5	Block Status Flag. Shall be managed by software.
6-7	Logical Block Address. Managed by NFC through NFLOG register (see Section "Logical Block Address").
8-10	ECC Area-2. Managed by NFC.
11-12	Logical Block Address. Managed by NFC through NFLOG register (see Section "Logical Block Address").
13-15	ECC Area-1. Managed by NFC.

The bytes which are not managed by the NFC are written to FFh.

**Write Session**

The spare zone is processed after the 'data zone'.

The NFC will initialize the byte at offset 3 with the byte contained in the NFUDAT register, and the 'Logical Block Address' (offsets 6-7, also duplicated at offsets 11-12) with the 2-bytes-descriptor stored in NFLOG (see Table 198, page 180 for more details).

Then the ECC is written at position 13, 14 and 15 for the ECC group 1 (from data byte 0 to data byte 255), and at position 8, 9 and 10 for ECC group 2 (from data byte 256 to data byte 511).

The ECC used can detects 2 wrong bits or more, and correct one bit.

**Read Session**

The NFC does only check (depending configuration explained in the next chapter) the ECC (ECC-1 and ECC-2).

**Spare Zone Management**

The way the spare zone is handled depends on 3 bits: the SPZEN bit in NFCON which is the automatic management enable bit, the ECCEN which is the ECC management enable bit and the ECCRDYE bit which is the ECC ready interrupt enable bit. Table 197 summarizes the spare zone behavior according to those control bits. Following section give detail on the management modes.

**Table 197. Spare Zone Management Modes**

SPZEN	ECCEN	ECCRDYE	Description
0	0	X	<b>Spare Zone Management Mode 1</b> The spare zone is not managed by the NFC.
1	1	0	<b>Spare Zone Management Mode 2</b> The spare zone is entirely managed by the NFC.
X	1	1	<b>Spare Zone Management Mode 3</b> The spare zone is not automatically managed by the NFC. However, an interrupt is triggered when the ECC FIFO is full, so after each 512 bytes processed. The user must program/verify the spare zone.

SPZEN	ECCEN	ECCRDYE	Description
0	1	0	<b>Not Supported</b> This configuration is reserved and must not be programmed.
1	0	X	<b>Not Supported</b> This configuration is reserved and must not be programmed.

### Spare Zone Mode 1

The spare zone is not managed by the NFC. The data zone is contiguous.

The user sends the commands to prepare the page for read or write. The data flow starts when the READ or WRITE bits are set by the user (write in NFACT). The NFC did not manage the spare zone, and did not stop when the ECC FIFO is full. Thus, NFC stops when it reaches the end of the data zone, or when it receives a STOP action.

### Spare Zone Mode 2

The spare zone is entirely managed by the NFC. The ECC is computed when the data flow starts. Each 256 bytes met, a 3-bytes ECC is built and stored in an ECC FIFO. When the ECC FIFO is full, the NFC stops the flow control to the DFC, and process the spare zone (ECC, logical value, parity... described later).

If the data flow stops before the end of the data zone, the user has the responsibility to stop the NFC and to program the spare zone.

The NFC will stop (idle mode) when it meet the end of the page. In this case, according to NECC, the controller will program/verify the appropriate spare zone(s). Let's take an example with 2kB memories:

- if the flow starts from the beginning of the page, NECC is 4 and the 4 spare zones will be verified or checked
- if the flow starts at offset 512, NECC is 3 and the 3 last spare zones of the page be verified or checked.
- etc.

Note that;

- For WRITE session, the byte at offset 2 is written to 0 (ECC valid) when the spare zone is written.
- For READ session, the ECC is verified only if the ECC is valid (byte at offset 2 is 0).

This mechanism ensures that the ECC is verified when it is valid.

This mode is particularly well suited for 512B and 2kB memories. For other kind of memories, mode 3 is preferable.

### Spare Zone Mode 3

The spare zone is not automatically managed by the NFC. The ECC is computed and stored in the ECC FIFO. When the ECC FIFO is full, the flow control is stopped and an interrupt is sent. The NFC returns to the idle state.

For 512B memories, the ECCRDYI interrupt is always triggered after 512 data bytes seen.

For 2kB memories and higher memories, the ECCRDYI interrupt is always triggered after 2048 data bytes seen.

The ECC engine is reset after a write in the NFCMD register. NECC gives the number of ECC in the FIFO.

Depending on the mapping of the page, the user have the possibility to:

- send the right events to program/verify the spare zone (reading the ECC FIFO). The READ or WRITE bits must be set (write in NFACT) to resume the data transfer, until the end of the page or an STOP action. The firmware shall also re-initialize the ECC FIFO by writing to NFECC.

- read the ECC FIFO, (keeping the ECCs in memory), re-initialize it, resume the data transfer, and to write all the ECC bytes at the end of the page.

### Logical Block Address

In order to automatically and properly fill the spare zone, the logical block address must be provided to the NFC. This is done by writing a 2-bytes descriptor byte by byte to the NFLOG register according to Table 198. The first byte written is byte 0. The logical block addresses must be updated each time the data flow reaches the beginning of new logical blocks.

**Table 198.** Logical Block Address descriptor Content

Byte Offset	Byte Mnemonic	Description
0	LBAH	Logical Block Address (MSB).
1	LBAL	Logical Block Address (LSB).

Reset Value = 0000 0000b for each byte.

In order to keep SMC compatibility, LBA will be organized as follow:

```

0 0 0 1 0 A A A
A A A A A A A P

```

Header 00010b and parity “P” are handled by software. “A” represents the logical block address.

### End of Data Transfer

When the data transfer stops, an interrupt is sent by the DFC macro to the CPU. The CPU has then to stop the NFC macro by sending a STOP action. This action can also be considered as an abort signal in a streaming mode. A STOP action makes the NFC return cleanly to the idle state (NFRUN cleared): it does not stop a spare area processing.

### End of Transfer Closing

When the NFC stops following a STOP action, in the case of a write session, the user must properly stop the page programming by copying old sectors to the new page. Moreover, the spare zone shall also be managed by the software.

To do this, the user needs to know where the NFC stopped: the NFBPH and NFBPL registers contain the byte position of the next data to be read or written. For example, it contains 0 after a reset, and 528 if the controller stops in a 512B page after the spare zone processing.

This register is incremented each time a byte is read through NFDATF or written through NFDAT or NFDATF, spare zone included.

A read of NFDAT or NFADC does not increment the NFBP counter.

The NFBP counter can be updated by software. Anyway, this shall be done in debug mode, and only when the NFC is not running.

Moreover, the NECC counter is updated when the controller reaches the end of the page. It gives the number of ECC that is ready to be written/updated. This feature shall be used when the flow does not start from the beginning of a page. For example, it contains 3 if the flow starts at offset 512 till the end of the page. In this situation, the three last ECC can be written/checked.

### Security Unit

The Security Unit provides hardware mechanisms to protect NF content from any firmware crash and prevent data loss and provides data recovery capability through ECC management.

## Write Protection

The NFC provides a hardware mechanism to protect full or part of the memory against any spurious writing. This is achieved by using the  $\overline{\text{NFWP}}$  signal and connecting it to the WP pins of the memories.

The  $\overline{\text{NFWP}}$  signal is automatically asserted in the following conditions:

- The internal voltage is out of specified value (brown-out detection)
- An external reset has been applied to the device
- A watchdog reset has been triggered (bad code execution)
- A write or erase to the protected area has been triggered (bad code execution)

## User Whole Memory Protection

The user has the possibility to protect all the flash devices (NF and SMC) by asserting the external  $\overline{\text{NFWP}}$  signal. This is achieved by clearing the NFWP bit in NFCON. All the memories are protected at the same time, i.e. NF and SMC if a SMC is present.

## Hardware Protected Area

A user defined area in the memories (a certain amount of blocks) can be locked against writing or erasing. This is done by giving to the controller the first protected block (FPB) address, the last protected block address (LPB) and the device number to be locked (PDEV). All this information is part of the Configuration Descriptor. Table 199 summarizes which device is locked or not.

The protected area is practically used for user firmwares, codec firmwares, fonts and other configuration data.

**Table 199.** Protected Device versus PDEV Value

PDEV3	PDEV2	PDEV1	PDEV0	Description
0	0	0	0	No locked devices
x	x	x	1	The blocks [FPB; LPB] of NF device 0 are locked
x	x	1	x	The blocks [FPB; LPB] of NF device 1 are locked
x	1	x	x	The blocks [FPB; LPB] of NF device 2 are locked
1	x	x	x	The blocks [FPB; LPB] of NF device 3 (SMCEN=0) or of SMC (SMCEN=1) are locked

Then, if a device is protected, the following policy is applied:

- If FPB is lower than LPB, the protected area is a contiguous area starting from FPB to LPB.
- If FPB is higher than LPB, there are two protected areas: any block address that is below LPB and any block address that is above FPB.
- If FPB is equal to LPB, all the flash is protected. This is the default behavior.

**Figure 81. Nand Flash Write Protection Scheme**

Since the  $\overline{\text{NFWP}}$  signal state is part of the device status, the user can detect a fault by reading it.

### ECC Error Management

When an ECC error is detected, the ECCERRI flag is set in NFINT and the 4-byte ECC error FIFO is updated. The FIFO content is read byte by byte using the NFERR register as detailed in Table 200.

First byte of the FIFO returns a status if the error can or can not be corrected. If it can not be corrected other 3-byte FIFO are cleared, If it can be corrected, the following 3 bytes return the address of the byte in error within the page (2 bytes) and the address of the bit in error within the byte (1 byte).

For example, if the byte read at offset 1921 (starting from 0) in a 2K page is E3 (wrong) instead of A3:

- byte offset MSB will be 07h
- byte offset LSB will be 81h
- bit offset will be 06h

**Table 200. ECC Error Descriptor**

Offset	Description
0	<b>Error Identification Byte</b> Refer to Table 201 for information on byte content.
1	<b>First 256-byte group of the sector</b> Byte offset
2	<b>Second 256-byte group of the sector</b> Byte offset
3	<b>Bit offset in the byte</b> Refer to Table 201 for information on byte content.

**Table 201. ECC Error Identification Byte**

7	6	5	4	3	2	1	0
0	0	0	0	SHERRID1	SHERRID0	FHERRID1	FHERRID0

Bit Number	Bit Mnemonic	Description
7-0	0	<b>Reserved</b> The value read from these bits is always 0.
3-2	SHERRID1-0	<b>Second Half Error Id Flag</b> Id of the error in the second "256-byte" group of the sector. 1: Correctable error. 2: Not correctable error. 3: Not correctable error in the ECC. Anyway, the data is good.
1-0	FHERRID1-0	<b>First Half Error Id Flag</b> Id of the error in the first "256-byte" group of the sector. 1: Correctable error. 2: Not correctable error. 3: Not correctable error in the ECC. Anyway, the data is good.

**Table 202.** ECC ERror Identification Byte

7	6	5	4	3	2	1	0
0	0	SHFB2	SHFB1	SHFB0	FHFB2	FHFB1	FHFB0

Bit Number	Bit Mnemonic	Description
7-6	-	<b>Reserved</b> The value read from these bits is always 0.
5-3	SHFB2:0	<b>Second Half Fail Bit Flag</b>
2-0	FHFB2:0	<b>First Half Fail Bit Flag</b>

**Card Unit**

**Enable**

Smartmedia or XD card management is enabled by setting SMCEN bit in SCFG1 register as detailed in Section "Configuration Descriptor" where specific configuration must also be set.

**Card Detect Input**

As shown in Figure 82 the SMINS (SMC/XD Card Detect) input implements an internal pull-up, in order to provide static high level when card is not present in the socket.

SMINS level is reported by SMCD bit<sup>(1)</sup> in NFSTA.

As soon as SMC is enabled, all level modifications on SMINS input from H to L or from L to H (card insertion or removal) set SMCTI, the SM Card Toggle Interrupt flag in NFINT.

Note: 1. SMCD bit is not relevant until SMC management is enabled.

**Figure 82.** Card Detection Input Block Diagram

## Card Lock Input

As shown in Figure 83 the  $\overline{\text{SMLCK}}$  (SMC/XD Lock) input implements an internal pull-up, in order to provide static high level when card is not present in the socket.

$\overline{\text{SMLCK}}$  level is reported by SMLCK bit<sup>(1)</sup> in NFSTA register.

Note: 1. SDWP bit is not relevant until SMC management is enabled and a card is present in the socket (SMCD = 0).

**Figure 83.** Card Write Protection Input Block Diagram

## Interrupt Unit

As shown in Figure 84, the NF controller implements five interrupt sources reported in SMCTI, ILGLI, ECCRDYI, ECCERRI, STOPI flags in NFINT register. These flags must be cleared by software when processing the interrupt service routine.

All these sources are enabled separately using SMCTE, ILGLE, ECCRDYE, ECCERRE, STOPE enable bits respectively in NFIEN register.

The interrupt request is generated each time an enabled flag is set, and the global NFC controller interrupt enable bit is set (ENFC in IEN1 register).

**Figure 84.** NFC Controller Interrupt System

There are 2 kinds of interrupts: processing (i.e. their generation is part of the normal processing) and exception (i.e. their generation correspond to error cases).

Processing interrupts are generated when:

- running to not running state transition (STOPI)
- ECC ready for operation (ECCRDYI)
- SMC insertion or removal (SMCTI)

Exception Interrupts are generated when the following events are met:

- ECC error (ECCERRI)

- or illegal operation (ILGLI)
  - Attempt to access a NF device which is not declared (e.g. DEV= 4 while NUMDEV= 2)
  - Write of events (NFDATF, NFDAT, NFCMD, NFADC, NFADR) while NFC is running (NFRUN= 1).  
Note that writing in NFACT while NFC is running (RUN=1) does not lead to an ILGLI interrupt.

As soon as an enabled interrupt is triggered, the NFC becomes not running (NFRUN= 0).

## Registers

**Table 203.** NFCFG Register

NFCFG (1.99h) – Nand Flash Controller Configuration Register

7	6	5	4	3	2	1	0
NFGD7	NFGD6	NFGD5	NFGD4	NFGD3	NFGD2	NFGD1	NFGD0

Bit Number	Bit Mnemonic	Description
7-0	NFGD7:0	<b>Nand Flash Configuration 8-byte Data FIFO</b> <b>Read Mode</b> Reading from this register resets the FIFO manager. <b>Write Mode</b> Write 8 bytes of data to update the NFC configuration registers according to Table 189.

Reset Value = 0000 0000b

**Table 204.** NFLOG Register

Reset Value = 0000 0000b

## MMC/SD Controller

The AT85C51SND3B derivatives implement a MMC/SD controller allowing connecting of MMC and SD cards in 1-bit or 4-bit modes. For MMC, 4-bit mode rely on the MMC Specification V4.0.

The MMC/SD controller interfaces to the C51 core through the following special function registers:

MMCON0, MMCON1, MMCON2, the three MMC control registers (see Table 222 to Table 224); MMBLP, the MMC Block Length register (see Table 225); MMSTA, the MMC status register (see Table 226); MMINT, the MMC interrupt register (see Table 227); MMMSK, the MMC interrupt mask register (see Table 228); MMCMD, the MMC command register (see Table 229); and MMDAT, the MMC data register (see Table 230).

As shown in Figure 85, the MMC controller is based on four functional blocks: the clock generator that handles the SDCLK (formally the MMC/SD CLK) output to the card, the command line controller that handles the SDCMD (formally the MMC/SD CMD) line traffic to or from the card, the data line controller that handles the SDDAT (formally the MMC/SD DAT) line traffic to or from the card, and the interrupt controller that handles the MMC controller interrupt sources. These blocks are detailed in the following sections.

Figure 86 shows the external components to add for connecting a MMC or a SD card to the AT85C51SND3B. SDDAT0 and SDCMD signals are connected to pull-up resistors. Value of these resistors is detailed in the Section "DC Characteristics", page 242.

**Figure 85.** MMC Controller Block Diagram

**Figure 86.** MMC Connection

## Clock Generator

The MMC clock is generated based on the clock generator as detailed in Section "MMC Clock Generator", page 32. As soon as MMCEN bit in MMCON2 is set, the MMC controller receives its system clock. The MMC command and data clock is generated on SDCLK output and sent to the command line and data line controllers.

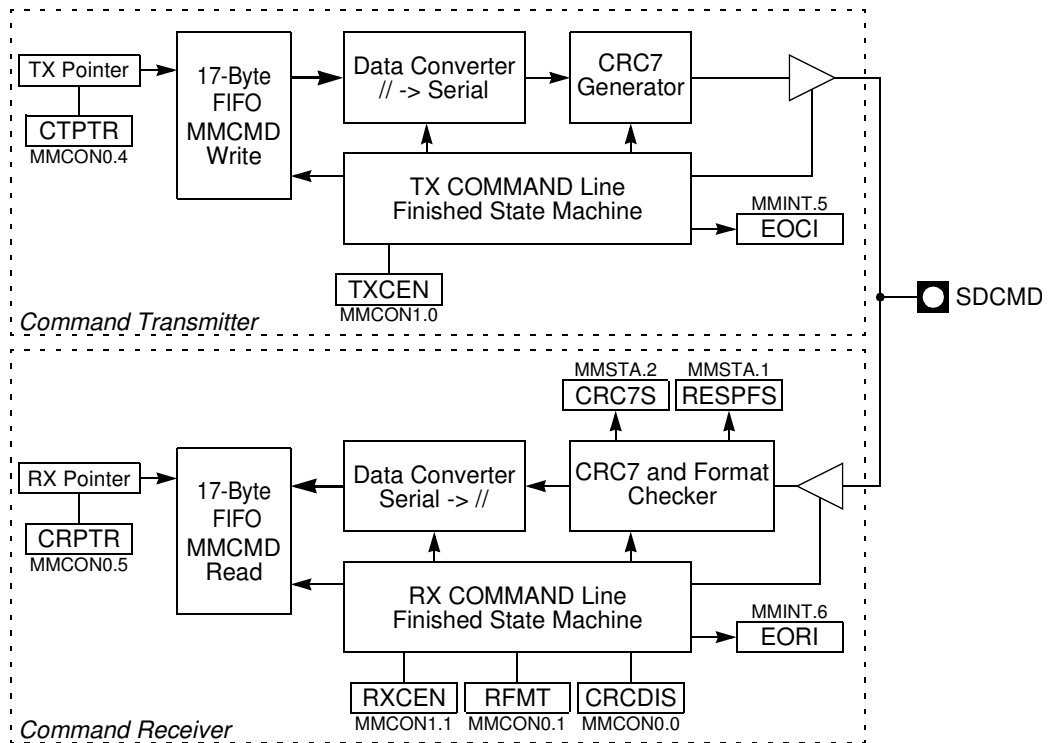

## Command Line Controller

As shown in Figure 87, the command line controller is divided in 2 channels: the command transmitter channel that handles the command transmission to the card through the SDCMD line and the command receiver channel that handles the response recep-

tion from the card through the SDCMD line. These channels are detailed in the following sections.

**Figure 87.** Command Line Controller Block Diagram

**Command Transmitter**

For sending a command to the card, the command index (1 Byte) and argument (4 Bytes) must be loaded in the command transmit FIFO using the MMCMD register. Before starting transmission by setting the TXCEN bit in MMCON1 register, software must first configure:

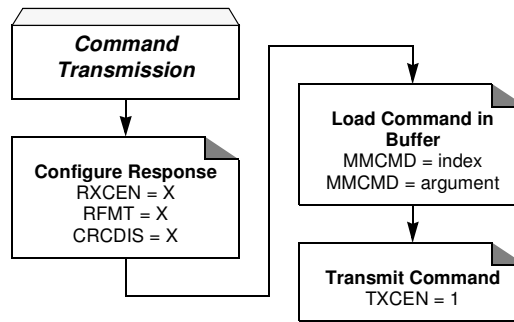

- RXCEN bit in MMCON1 register to indicate whether a response is expected or not.
- RFMT bit in MMCON0 register to indicate the response size expected.
- CRCDIS bit in MMCON0 register to indicate whether the CRC7 included in the response will be computed or not. In order to avoid CRC error, CRCDIS may be set for response that do not include CRC7.

Figure 88 summarizes the command transmission flow.

The TXCEN flag is set until the end of transmission. The end of the command transmission is signalled by the EOCI flag in MMINT register becoming set. This flag may generate an interrupt request as detailed in Section “Interrupt”. The end of the command transmission also clears the TXCEN flag.

Command loading may be aborted by setting and clearing the CTPTR bit in MMCON0 register which resets the write pointer to the transmit FIFO.

**Figure 88.** Command Transmission Flow

## Command Receiver

The end of the response reception is signalled by the EORI flag in MMINT register. This flag may generate an interrupt request as detailed in Section "Interrupt". When this flag is set, 2 other flags (RXCEN in MMCON1 register and CRC7S in MMSTA register) give a status on the response received. RXCEN is cleared when the response format is correct or not: the size is the one expected (48 bits or 136 bits) and a valid End bit has been received, and CRC7S indicates if the CRC7 computation is correct or not. The Flag CRC7S is cleared when a command is sent to the card and updated when the response has been received.

Response reading may be aborted by setting and clearing the CRPTR bit in MMCON0 register which resets the read pointer to the receive FIFO.

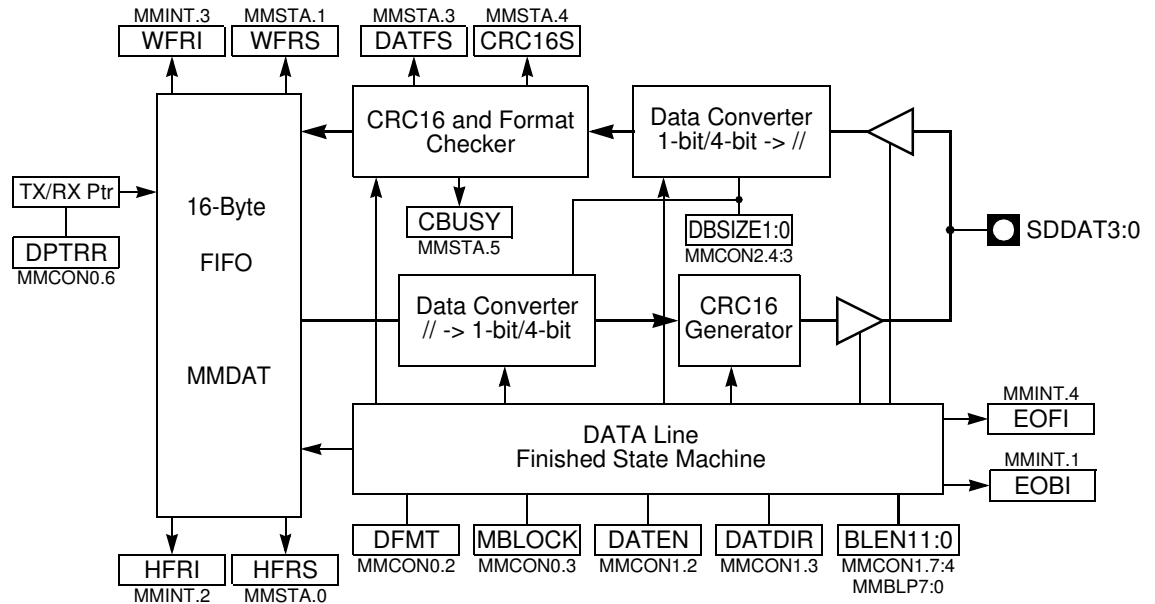

According to the MMC specification delay between a command and a response (formally  $N_{CR}$  parameter) can not exceed 64 MMC clock periods. To avoid any locking of the MMC controller when card does not send its response (e.g. physically removed from the bus), a time-out timer must be launched to recover from such situation. In case of time-out the command controller and its internal state machine may be reset by setting and clearing the CCR bit in MMCON2 register.

This time-out may be disarmed when receiving the response.

**Data Line Controller**

As shown in Figure 89, the data line controller is based on a 16-Byte FIFO used both by the data transmitter channel and by the data receiver channel. Data transfer can be handled in transmission or received by the Data Flow Controller (see Section “Data Flow Controller”, page 78) or by the C51 using MMDAT register.

**Figure 89.** Data Line Controller Block Diagram

**Bus Width Control**

The data line controller supports the SD card and the new MMC 4.0 4-bit bus mode allowing higher transfer rate. The 4-bit bus width is controlled by software by setting the DBSIZE1:0 bits in MMCON2 register according to Table 220. In case of 1-bit bus width (card default), SDDAT0 is used as SDDAT line and SDDAT3:1 lines are released as I/O port.

**Table 220.** Data Bus Size

DBSIZE1:0	Bus Size
0	1-bit SDDAT0 data bus.
1	4-bit SDDAT3:0 data bus.
2-3	Reserved for future use, do not program these values.

**FIFO Implementation**

The 16-Byte FIFO is managed using 1 pointer and four flags indicating the status ready of whole or half FIFO.

Pointer value is not accessible by software but can be reset at any time by setting and clearing DPTRR bit in MMCON0 register. Resetting the pointer is equivalent to abort the writing or reading of data.

FIFO flags indicate when FIFO is ready to be read in receive mode or to be written in transmit mode. WFRI is set when 16 bytes are available in writing or reading. HFRI is set when 8 bytes are available. These flags are cleared when read. These flags may generate an interrupt request as detailed in Section “Interrupt”. WFRS and HFRS give the status of the FIFO. They are set when respectively 16 bytes or 8 bytes are ready to be read or written depending on the receive or transmit mode.

## Data Configuration

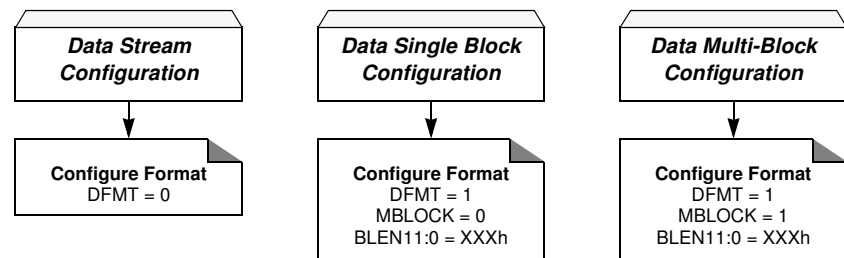

Before sending or receiving any data, the data line controller must be configured according to the type of the data transfer considered. This is achieved using the Data Format bit: DFMT in MMCON0 register. Clearing DFMT bit enables the data stream format while setting DFMT bit enables the data block format. In data block format, the single or multi-block mode must also be configured by clearing or setting the MBLOCK bit in MMCON0 register and the block length in bytes using BLEN11:0<sup>(1)</sup> bits in MMCON1 and MMBLP according to Table 221. Figure 90 summarizes the data modes configuration flows. BLEN can have any value between 1 to 2048.

**Table 221.** Block Length Programming

Register	Description
<b>MMBLP7:0</b>	Block Size LSB: BLEN11:8
<b>MMCON1.7:4</b>	Block Size MSB (LSN): BLEN7:0

Note: 1. BLEN = 1 to 2048

**Figure 90.** Data Controller Configuration Flows

## Data Transmitter

### Configuration

For transmitting data to the card the data controller must be configured in transmission mode by setting the DATDIR bit in MMCON1 register.

Figure 91 summarizes the data stream transmission flows in both polling and interrupt modes while Figure 92 summarizes the data block transmission flows in both polling and interrupt modes, these flows assume that block length is greater than 16 Bytes.

### DFC Data Loading

In case the data transfer is handled by the DFC, a DFC channel must be configured with the MMC controller as destination peripheral. The programmed number of data is autonomously transferred from the source peripheral to the FIFO without any intervention from the firmware.

In case both FIFO are empty (e.g. source peripheral busy), card clock is automatically frozen stopping card data transfer thanks to the controller automatic flow control.

### C51 Data Loading

In case the data transfer is handled by the C51<sup>(1)</sup>, data is loaded byte by byte in the FIFO by writing to MMDAT register. Number of data loaded may vary from 1 to 16 Bytes. Then if necessary (more than 16 Bytes to send) software must ensure that all FIFO or half FIFO becomes empty (WFRS or HFRS set) before loading 16 or 8 new data.

In case both FIFO are empty, card clock is automatically frozen stopping card data transfer thanks to the controller automatic flow control.

Note: 1. An enabled DFC transfer always takes precedence on a C51 transfer, it is under software responsibility not to write to MMDAT register while a DFC transfer is enabled.

### *Data Transmission*

Transmission is enabled by setting DATEN bit in MMCON1 register. FIFO must be filled after this flag is set.

If at least the FIFO is half full, data is transmitted immediately when the response to the write command has already been received, or is delayed after the reception of the response if its status is correct. In both cases transmission is delayed if a card sends a busy state on the data line until the end of this busy condition.

According to the MMC specification, the data transfer from the host to the card may not start sooner than 2 MMC clock periods after the card response was received (formally  $N_{WR}$  parameter). To address all card types, this delay can be programmed using DATD1:0 bits in MMCON2 register from 3 MMC clock periods when DATD1:0 bits are cleared to 9 MMC clock periods when DATD1:0 bits are set, by step of 2 MMC clock periods.

### *End of Transmission*

In data stream mode, the end of a data frame transmission is signalled by the EOFI flag in MMINT register. This flag may generate an interrupt request as detailed in Section "Interrupt". It is set, after reception of the End bit. This assumes that the STOP command has previously been sent to the card, which is the only way to stop stream transfer.

In data single block mode, the end of a data frame transmission is signalled by the EOFI flag in MMINT register. This flag may generate an interrupt request as detailed in Section "Interrupt". It is set after the end of busy signal on SDDAT0 line.

After reception of the CRC status token, two other flags in MMSTA register: DATFS and CRC16S report a status on the frame sent. DATFS indicates if the CRC status token format is correct or not, and CRC16S indicates if the card has found the CRC16 of the block correct or not. CRC16S must be reset by software by setting DCR bit in MMCON2 register.

EOBI flag in MMINT register is also set at the same time as EOFI, and may generate an interrupt request as detailed in Section "Interrupt"

In data multi block mode, the end of a data frame transmission is signalled by the EOFI flag in MMINT register. This flag may generate an interrupt request as detailed in Section "Interrupt". It is set after the end of busy signal on SDDAT0 line. This assumes that the STOP command has previously been sent to the card, which is the only way to stop stream transfer.

The end of a block transmission is signalled by the EOBI flag in MMINT register. This flag may generate an interrupt request as detailed in Section "Interrupt". It is set after the end of busy signal on SDDAT0 line.

After reception of the CRC status token of a block, two other flags in MMSTA register: DATFS and CRC16S report a status on the frame sent. DATFS indicates if the CRC status token format is correct or not, and CRC16S indicates if the card has found the CRC16 of the block correct or not. CRC16S must be reset by software by setting DCR bit in MMCON2 register.

### *Busy Status*

The card uses a busy token during a block write operation. This busy status is reported by the CBUSY flag in MMSTA register.

The busy signal is set to 0 by the card after the CRC token. At the end of busy signal, the flag DATEN is cleared and EOFI flag is set.

Note: some cards do not respect MMC specification, and the busy status is reported too late on the dat0 line, considering the  $N_{st}$  parameter. So CBUSY flag is not set. In this case, status of the card must be asked with a card command.

Figure 91. Data Stream Transmission Flows

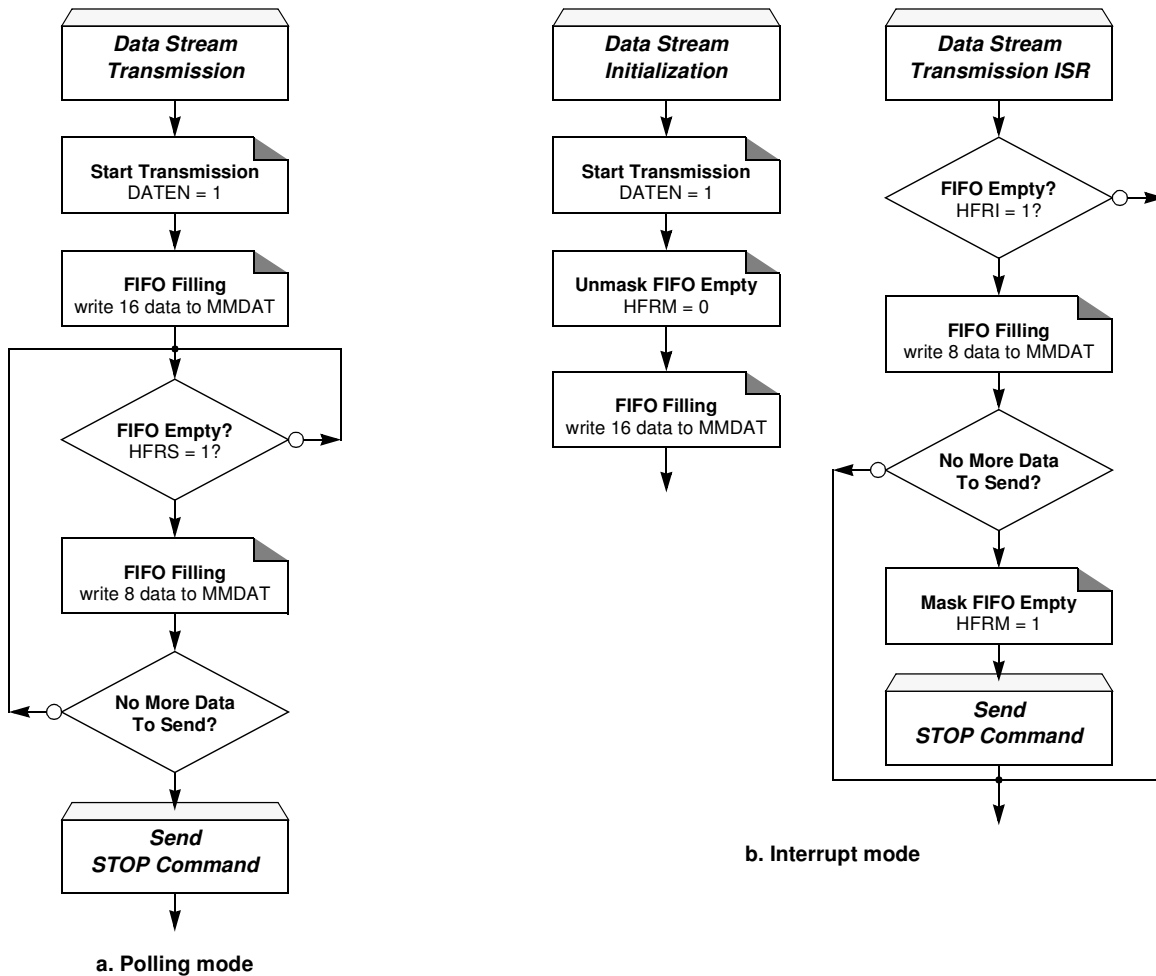

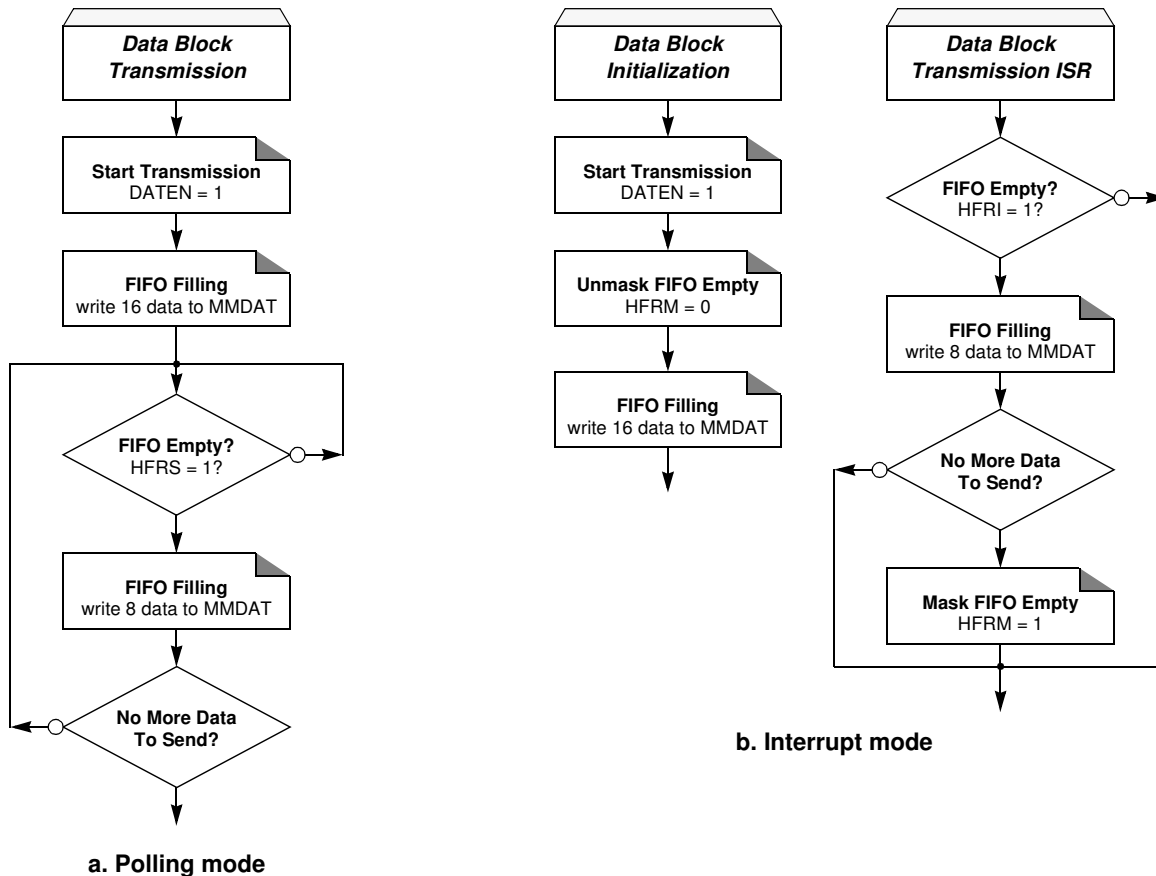

Figure 92. Data Block Transmission Flows

Data Receiver

Configuration

To receive data from the card the data controller must be configured in reception mode by clearing the DATDIR bit in MMCON1 register.

Figure 93 summarizes the data stream reception flows in both polling and interrupt modes while Figure 94 summarizes the data block reception flows in both polling and interrupt modes, these flows assume that block length is greater than 16 Bytes.

Data Reception

Reception is enabled by setting DATEN bit in MMCON1 register. The end of a data frame (block(s) or stream) reception is signalled by the EOFI flag in MMINT register. In multiblock mode, OEBI flag signals the reception of one block. These flags may generate an interrupt request as detailed in Section "Interrupt". When EOFI flag is set, 2 other flags in MMSTA register: DATFS and CRC16S give a status on the frame received. DATFS indicates if the frame format is correct or not: a valid End bit has been received, and CRC16S indicates if the CRC16 computation is correct or not. CRC16S must be reset by software by setting DCR bit in MMCON2 register. In case of data stream CRC16S has no meaning and stays cleared. DATEN flag is cleared when EOFI is set.

According to the MMC specification data transmission from the card starts after the access time delay (formally  $N_{AC}$  parameter) beginning from the End bit of the read command. To avoid any locking of the MMC controller when card does not send its data (e.g. physically removed from the bus), a time-out timer must be launched to recover

from such situation. In case of time-out, the data controller and its internal state machine may be reset by setting and clearing the DCR bit in MMCON2 register.

This time-out may be disarmed after receiving 8 data (HFRS flag set) or after receiving end of frame (EOF1 flag set) in case of block length less than 8 data (1, 2 or 4).

### DFC Data Reading

In case the data transfer is handled by the DFC, a DFC channel must be configured with the MMC controller as source peripheral. The programmed number of data is autonomously transferred from the FIFO to the destination peripheral without any intervention from the firmware.

In case both FIFO are full (e.g. destination peripheral busy), card clock is automatically frozen stopping card data transfer thanks to the controller automatic flow control.

### C51 Data Reading

In case the data transfer is handled by the C51<sup>(1)</sup>, data is read byte by byte from the FIFO by reading MMDAT register. Each time FIFO becomes full or half full (WFRI or HFR1 set), software is requested to flush this FIFO by reading 16 or 8 data.

In case FIFO is full, card clock is automatically frozen stopping card data transfer thanks to the controller automatic flow control.

Note: 1. An enabled DFC transfer always takes precedence on a C51 transfer, it is under software responsibility not to read from MMDAT register while a DFC transfer is enabled.

**Figure 93.** Data Stream Reception Flows

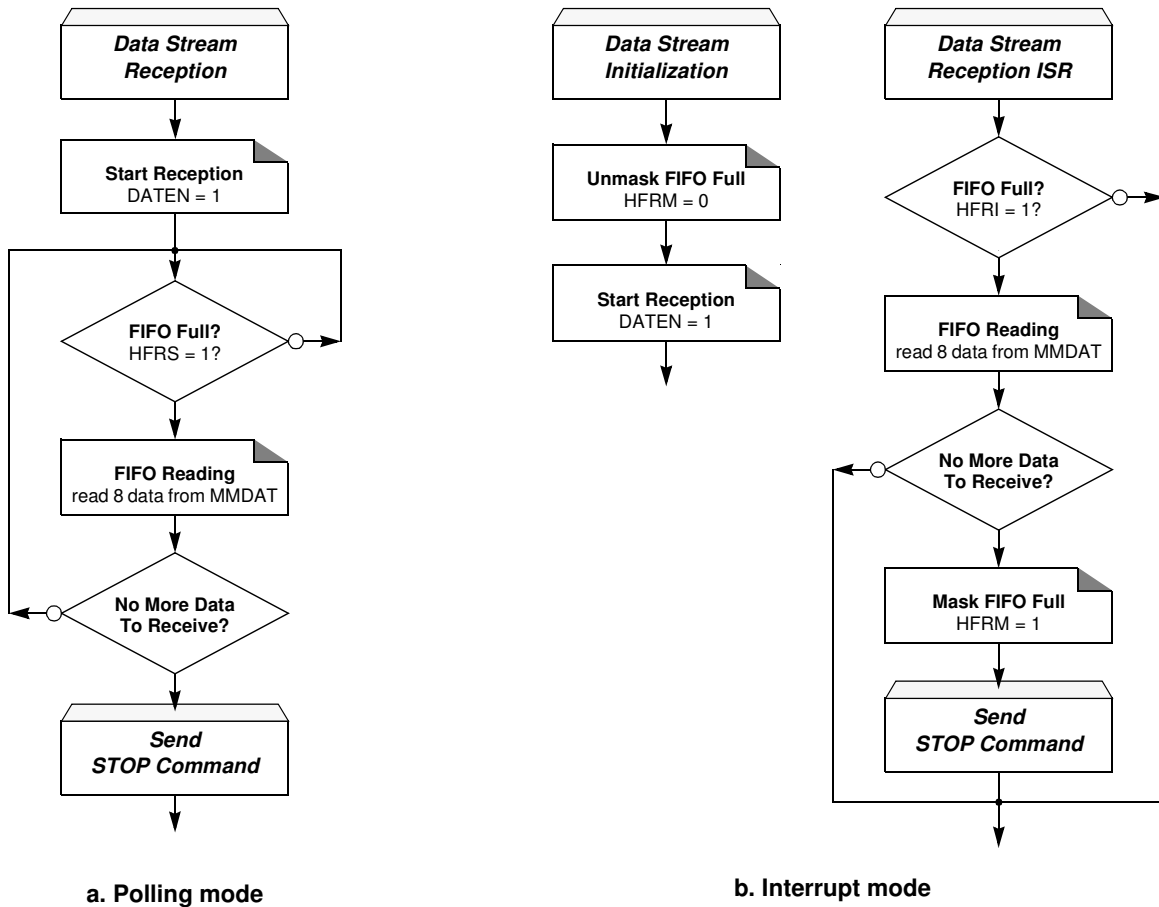

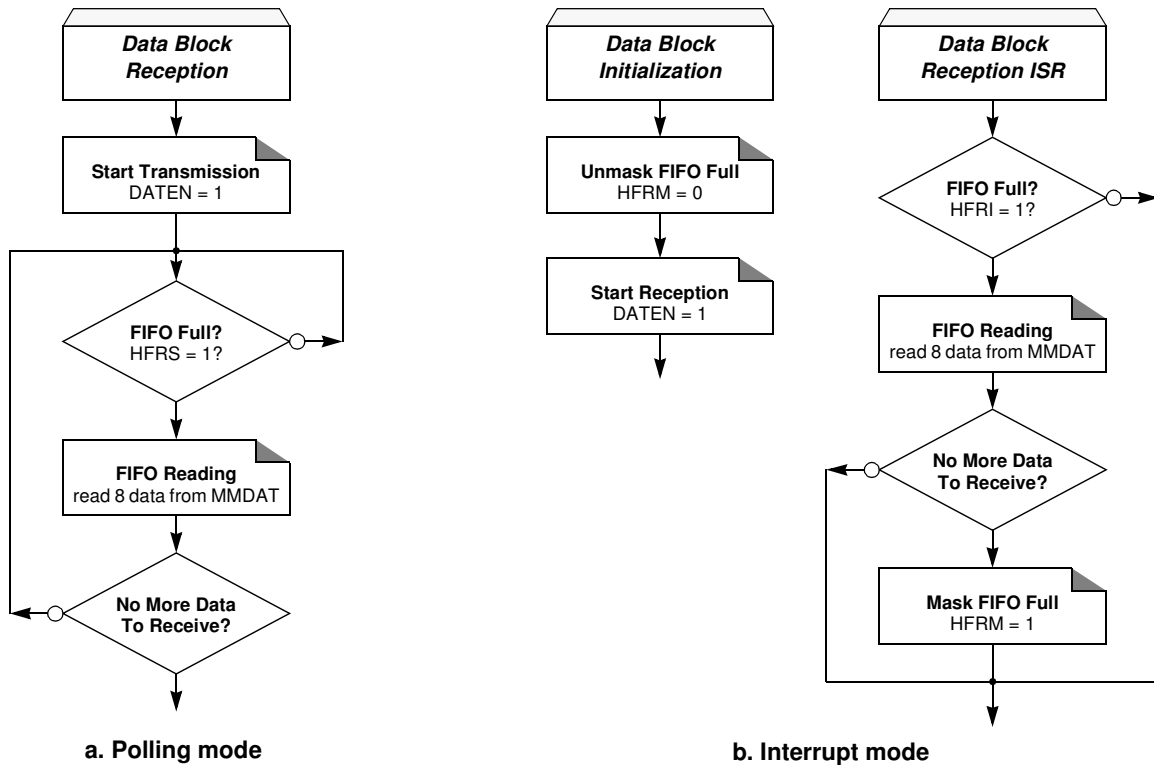

Figure 94. Data Block Reception Flows

## Card Management

### Card Detect Input

As shown in Figure 95 the  $\overline{\text{SDINS}}$  (MMC/SD Card Detect) input implements an internal pull-up, in order to provide static high level when card is not present in the socket.

$\overline{\text{SDINS}}$  level is reported by CDET bit<sup>(1)</sup> in MMSTA.

As soon as MMC controller is enabled, all level modifications on  $\overline{\text{SDINS}}$  input from H to L or from L to H (card insertion or removal) set CDETI, the Card Detect Interrupt flag in MMINT (see Table 227).

Note: 1. CDET bit is not relevant until MMC controller is enabled (MMCEN = 1).

Figure 95. Card Detection Input Block Diagram

### Card Lock Input

As shown in Figure 96 the  $\overline{\text{SDLCK}}$  (SD Lock) input implements an internal pull-up, in order to provide static high level when card is not present in the socket.

$\overline{\text{SDLCK}}$  level is reported by SDWP bit<sup>(1)</sup> in MMSTA register.

Note: 1. SDWP bit is not relevant until MMC controller is enabled (MMCEN = 1) and a card is present in the socket (CDET = 0).

**Figure 96.** SD Card Write Protection Input Block Diagram

## Interrupt

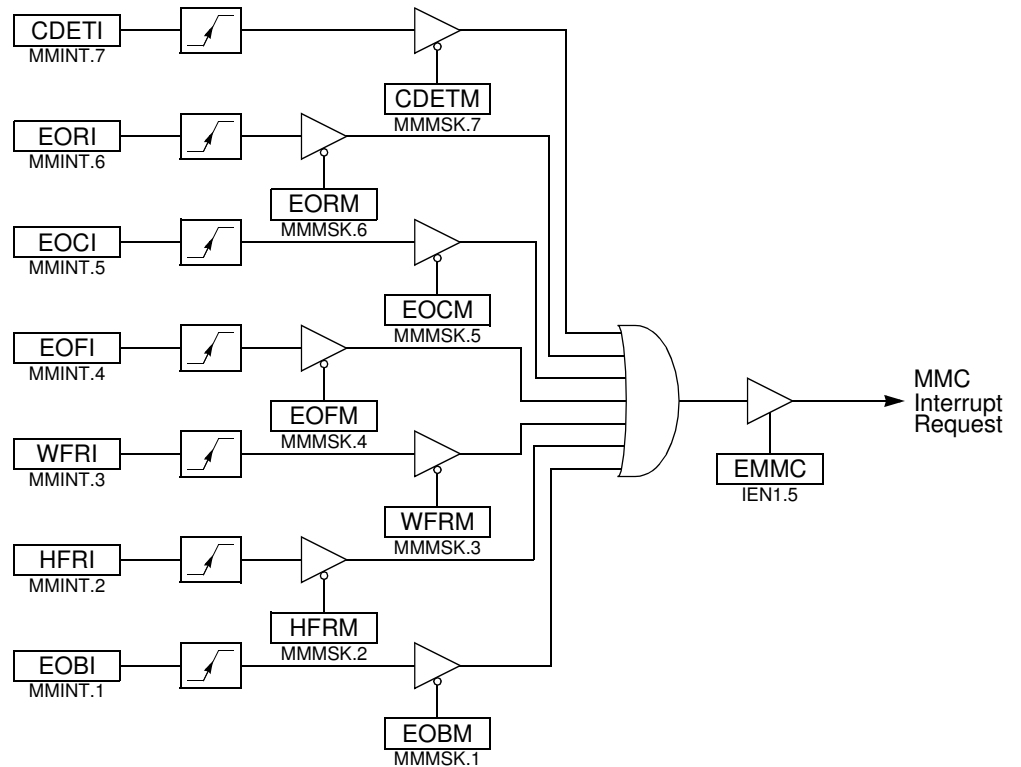

As shown in Figure 97, the MMC controller implements eight interrupt sources reported in CDETI, EORI, EOCI, EOFI, WFRI, HFRI and EOBI flags in MMCINT register. These flags are detailed in the previous sections.

All these sources are maskable separately using CDETM, EORM, EOCM, EOFM, WFRM, HFRM and EOBM mask bits respectively in MMMSK register.

The interrupt request is generated each time an unmasked flag is set, and the global MMC controller interrupt enable bit is set (EMMC in IEN1 register).

Reading the MMINT register automatically clears the interrupt flags (acknowledgment). This implies that register content must be saved, and tested flag by flag to be sure not to forget any interrupts.

**Figure 97.** MMC Controller Interrupt System

## Registers

**Table 222.** MMCON0 Register

MMCON0 (1.B1h) – MMC Control Register 0

7	6	5	4	3	2	1	0
-	DPTRR	CRPTR	CTPTR	MBLOCK	DFMT	RFMT	CRCDIS
Bit Number	Bit Mnemonic	Description					
7	-	<b>Reserved</b> The value read from this bit is always 0. do not set this bit					
6	DPTRR	<b>Data Pointer Reset Bit</b> Set to reset the read and write pointer of the data FIFO. Cleared by hardware after pointer reset is achieved.					
5	CRPTR	<b>Command Receive Pointer Reset Bit</b> Set to reset the read pointer of the receive command FIFO. Cleared by hardware after pointer reset is achieved.					
4	CTPTR	<b>Command Transmit Pointer Reset Bit</b> Set to reset the write pointer of the transmit command FIFO. Cleared by hardware after pointer reset is achieved.					
3	MBLOCK	<b>Multi-block Enable Bit</b> Set to select multi-block data format. Clear to select single block data format.					
2	DFMT	<b>Data Format Bit</b> Set to select the block-oriented data format. Clear to select the stream data format.					
1	RFMT	<b>Response Format Bit</b> Set to select the 48-bit response format. Clear to select the 136-bit response format.					
0	CRCDIS	<b>CRC7 Disable Bit</b> Set to disable the CRC7 computation when receiving a response. Clear to enable the CRC7 computation when receiving a response.					

Reset Value = 0000 0010b

**Table 223.** MMCON1 Register

## Parallel Slave Interface

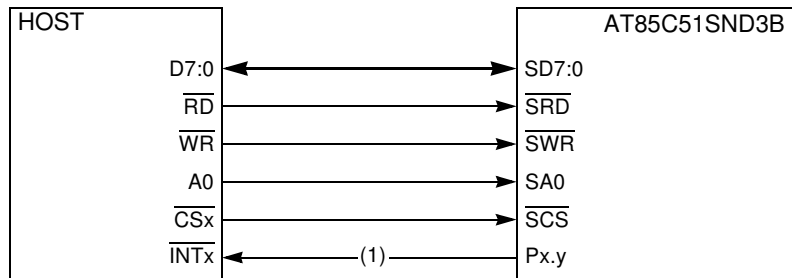

The AT85C51SND3B derivatives implement a Parallel Slave Interface (PSI) allowing parallel connection with a host for remote control and data transfer. By using this interface, the AT85C51SND3B can be seen as a multimedia co-processor and be remotely controlled by the host.

The main features of the PSI Interface are:

- ARM / I80 glueless interface capability
- 8-bit parallel data bus
- 1-bit address bus
- 16-byte FIFO with MCU interrupt capability
- Bi-directional multimedia bus connection through one DFC Channel

Figure 98 shows a typical PSI host connection. Interface consists in a 8-bit data bus, a 1-bit address bus and read and write signals along with a chip select.

**Figure 98.** Typical PSI Host Connection

Note: 1. Optional signal for slave to host signaling.

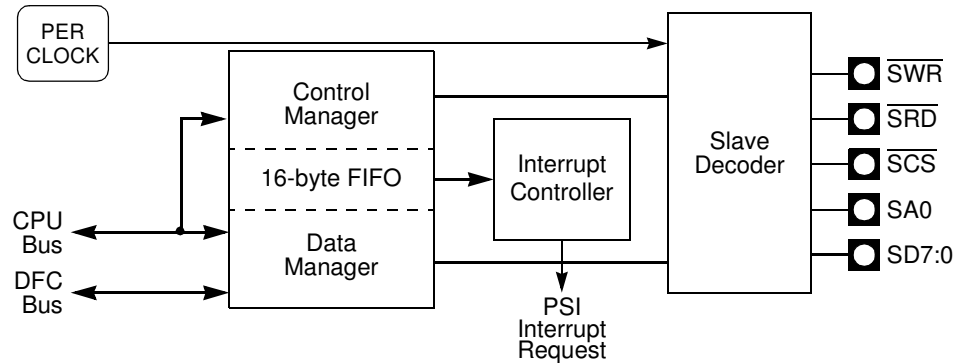

## Description

The C51 core interfaces with the PSI using the following Special Function Registers: PSICON (see Table 232) the control register, PSISTA (see Table 233) the status register, PSIDAT (see Table 234) the data register and PSISTH (see Table 235) the host status register.

The PSI is enabled by setting the PSEN bit in PSICON.

As soon as the PSI is enabled, I/O ports are programmed in input and I/O pull-ups are disabled.

**Figure 99.** PSI Block Diagram

## PSI Addressing

The AT85C51SND3B are accessible by a host in read or write at two different address locations by setting or clearing the SA0 address signal. The data management is

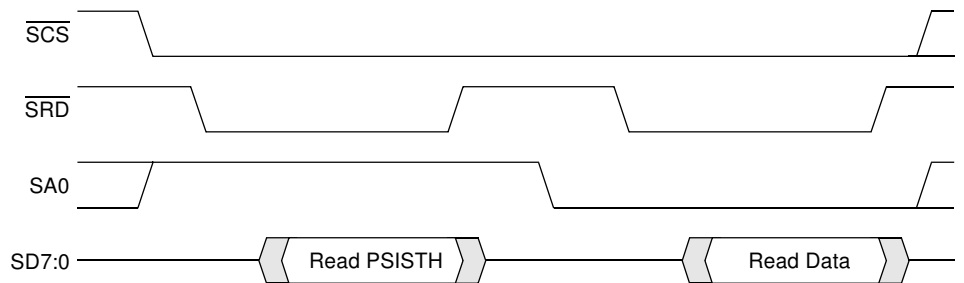

detailed in following sections and differs depending on SA0 level. Table 235 shows the addressing truth table. Figure 100 and Figure 101 show the read and write host cycles.

**Table 231.** PSI Addressing Truth Table

SA0	$\overline{\text{SRD}} / \overline{\text{SWR}}$	Selection
1	Read	Host reads the PSISTH register to get PSI status from both hardware and software.
1	Write	Host writes in the FIFO.
0	Read	<b>DFC transfer</b> (PSI is destination) Host reads data from the source peripheral through the FIFO. <b>CPU transfer</b> Host reads data from the FIFO.
0	Write	<b>DFC transfer</b> (PSI is source) Host writes data to the destination peripheral through the FIFO. <b>CPU transfer</b> Host writes data in the FIFO.

**Figure 100.** Host Read Waveforms

**Figure 101.** Host Write Waveforms

*Write Data Sampling*

In order to be compliant with hosts depending on write cycle timing, a delay from  $\overline{\text{SRW}}$  signal assertion can be programmed for sampling data written by the host. This delay is programmable from 0 to 7 peripheral clock periods using PSWS2:0 bits in PSICON. Figure 102 shows the write sampling delay waveform.

Depending on the system clock frequency, host may need to add wait states inside read or write cycles.

**Figure 102.** Write Data Sampling Configuration

**“SA0= H” Mode**

The “SA0= H” mode is particularly fitting control management over a protocol. Figure 103 shows a data cycle from host to device. Prior to send any data bytes, the host must take care of the PSI state by reading the AT85C51SND3B with SA0 signal set. This returns PSISTH: the host status register content. While PSHBSY bit in PSISTH is set, the host must not start sending data.

As soon as PSHBSY bit is released, the host can send up to 16 bytes of data. First data writing automatically sets PSBSY flag in PSISTA and consequently PSHBSY bit so that host knows that system is now busy and processing. An interrupt can be generated when PSBSY flag is set by enabling PSBSYE bit in PSICON while global PSI interrupt is enabled in IEN1 (see Figure 104).

The software can start reading and process the data after first byte reception. As soon as data processing is done, PSBSY flag is cleared and consequently PSHBSY bit so that host knows that system has finished processing. A software status can have been previously written to PSISTH for reporting to the host.

Note: If software reading is quicker than host writing, PSEMPY bit must be polled before reading new data byte.

**Figure 103.** Data Management (SA0 = H)

**“SA0= L” Mode**

The “SA0= L” mode is particularly fitting data transfer with huge amount of data. Transfer can be done in read and write using the DFC for high throughput or the CPU. After control processing (PSBSY cleared) and relying to the protocol, the host starts transferring data. In all cases the host which is the master controls the data transfer by reading from or writing to the slave.

*CPU Transfer*

In case of transfer handled by the CPU, the data transfer is done byte by byte. As the host runs usually quicker than the slave, a software handshake must be established to avoid underrun or overrun condition.

*DFC Transfer*

In case of transfer handled by the DFC, the slave can acknowledge its control processing (PSBSY cleared) as soon as destination (host write) or source (host read) is ready.

Host can then read or write by burst an amount of data defined by the protocol (see Section “Data Flow Controller”, page 78).  
 In order to avoid any underrun or overrun condition during burst transfer, host must be slower than the DFC destination peripheral (host write) or the DFC source peripheral (host read).

*Overrun - Underrun Conditions*

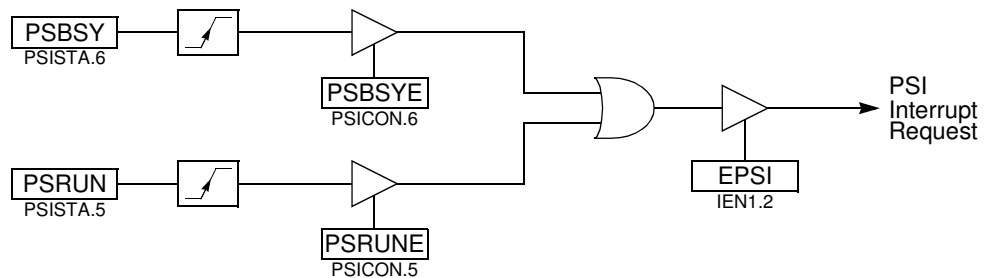

An overrun condition occurs when the hosts writes data quicker than the slave can consume it.  
 An underrun condition occurs when the host read data quicker than the slave can deliver it.  
 As soon as one of these two conditions is triggered, the PSRUN flag in PSISTA is set. An interrupt can be generated when PSRUN bit is set by enabling PSRUNE bit in PSICON while global PSI interrupt is enabled in IEN1 (see Figure 104).

- Notes:
1. Overrun and underrun conditions may appear in both transfer modes (CPU or DFC).
  2. In overrun condition, the data written by the host is discarded.
  3. In underrun condition, the data read by the host is the same as the previous one.

**Interrupts**

As shown in Figure 104, the PSI implements two interrupt sources reported in PSBSY and PSRUN flags in PSISTA. These flags are detailed in the previous sections.  
 These sources are enabled separately using PSBSYE, and PSRUNE enable bits respectively in PSICON.  
 The interrupt request is generated each time an enabled flag is set, and the global PSI interrupt enable bit is set (EPSI in IEN1 register).

**Figure 104.** PSI Controller Interrupt System

## Registers

7-0	PSD7:0	<b>Data Bits</b> Reading this register returns the data written by the host in the FIFO. Writing this register set data in the FIFO read later by the host.

Reset Value = 0000 0000b

## Serial I/O Port

The AT85C51SND3B derivatives implement a Serial Input/Output Port (SIO) allowing serial communication. By using this interface, the AT85C51SND3B can be seen as a multimedia co-processor and be remotely controlled by the host.

The main features of the SIO Interface are:

- Asynchronous mode (UART: Rx, Tx)
- Hardware flow control ( $\overline{\text{CTS}}$ ,  $\overline{\text{RTS}}$ )
- High speed baud rate generator
- 16-byte input buffer with MCU interrupt capability
- Bi-directional multimedia bus connection through one DFC Channel

Figure 105 shows a typical SIO host connection. Interface consists in a 2-bit receive/transmit bus and a 2-bit flow control bus.

**Figure 105.** Typical SIO Host Connection

## Description

The C51 core interfaces with the SIO using the following Special Function Registers: SCON, the SIO Control register (see Table 243); SFCON, the SIO Flow Control register (see Table 244); SINT, the SIO Interrupt Source register (see Table 245); SIEN, the SIO Interrupt Enable register (see Table 246); SBUF, the SIO Buffer register (see Table 247); SBRG0, SBRG1 and SBRG2, the SIO Baud Rate Generator registers (see Table 248 to Table 250). As shown in Figure 106 the SIO is based on three main functional blocks detailed in the following sections: the baud rate generator that generates an over-sampling clock for both receiver and transmitter, the receiver that handles the characters reception and the transmitter that handles the characters transmission.

## Data Transfer

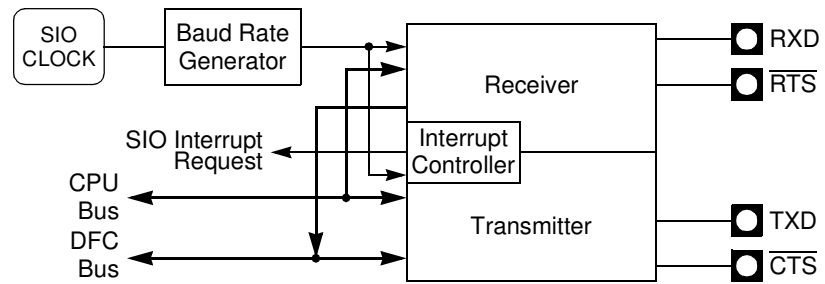

The data transfers can be handled completely by the C51 in full duplex, i.e. C51 manages character transmission by writing data to SBUF register and character reception by reading data from SBUF. It is obvious that using C51 for data transfer leads to low throughput. In order to increase throughput and take advantage of high bit rates up to 8Mbit/s, a DFC channel can be associated to the SIO in read or write (see Section “Data Flow Controller”, page 78). DFC can be used for data reception (SIO considered as source) or data transmission (SIO considered as destination). In both cases, the data transfer is still full duplex since C51 continues to handle transmission or reception but at lower throughput.

Table 236 summarizes the data transfer modes association. DFC usage is enabled as soon as a DFC transfer is enabled by selecting SIO as source or destination.

**Table 236.** Data Transfer Modes

Transfer Modes	Reception Handling	Transmission Handling
High Throughput Reception	DFC (SIO is source)	C51
High Throughput Transmission	C51	DFC (SIO is destination)
Low Throughput Transfer (default)	C51	C51

Figure 106. SIO Block Diagram

**Character Format**

The character consists of five fields: start, data, parity, stop and guard fields. Figure 107 shows a character example with 8 data bits, 1 parity bit, 2 stop bits and 2 guard bits.

Figure 107. Character Format Example

*Start Field*

The start field is fixed and composed of 1 bit transmitted or received at low level.

*Data Field*

The data field is composed of 7 or 8 bits by programming DLEN bit in SCON according to Table 237. The least significant bit is always first transmitted.

Table 237. Data Bit Number Selection

DLEN	Description
0	7-bit Data Length.
1	8-bit Data Length.

*Parity Field*

The parity field is optional and enabled by PBEN bit in SCON. This field is composed of 1 bit and its mode is programmable by PMOD1:0 bits in SCON according to Table 238.

Table 238. Parity Mode Selection

PMOD1	PMOD0	Description
0	0	MARK: high Level
0	1	SPACE: Low Level
1	0	EVEN: High Level if the number of bits at high level in the data field is even.
1	1	ODD: Low Level if the number of bits at high level in the data field is odd.

*Stop Field*

The stop field is composed of 1 or 2 bits transmitted or received at high level by programming STOP bit in SCON according to Table 239.

**Table 239.** Stop Bit Number Selection

STOP	Description
0	1 Stop Bit.
1	2 Stop Bits.

*Guard Field*

The guard field is not part of a character and is an optional inter-character spacing composed of 0 to 3 bits transmitted at high level by programming GBIT1:0 bits in SCON according to Table 240. The guard field allows transmitter to be compliant with connected host (overrun avoiding) and is emitted after the last stop bit of a character.

**Table 240.** Guard Field Size Selection

GBIT1	GBIT0	Description
0	0	0 guard bit inserted (default).
0	1	1 guard bit inserted.
1	0	2 guard bits inserted.
1	1	3 guard bits inserted.

**Baud Rate Generator**

The Baud Rate Generator is fed by the SIO clock as detailed in Section “SIO Clock Generator”, page 33. The maximum baud rate can be achieved by selecting the high frequency issued by a division of the PLL clock. The clock generated is an oversampling clock. The oversampling factor is programmable using OVRSF3:0 bits in SFCON with oversampling factor equal to OVRSF3:0 + 1 (e.g.: OVRSF3:0= 11 for a 12x oversampling).

**Baud Rate Calculation**

As shown in Figure 109, the baud rate generator is composed of an integer divider followed by a fractional divider. The baud rate formula is given by Figure 108. In this formula, variables must be chosen as followed:

- OVRSF  
The oversampling factor depends mainly on the frequency and the quality of the medium transporting the data. In any case, OVSF3:0 must not be less than 4 for proper majority vote in bit reception.
- ADIV  
Must be greater than BDIV and less than (K · OVRSF). K being the number of bit in a character (from 9 to 11).
- BDIV  
Must be greater than 1/ε according to the tolerance on the real baud rate BR<sub>R</sub> compare to the theoretical baud rate BR<sub>T</sub>.  
ε being the error:  $\epsilon = K \cdot |1/BB_T - 1/BR_R|$ .

Table 241 shows some programming values depending on the SIO frequency and considering an oversampling factor of 12 (OVERSF3:0= 11).

**Figure 108.** Baud Rate Formula

$$\text{Baud\_Rate} = \frac{F_{\text{SIO}} \cdot \text{BDIV}}{\text{ADIV} \cdot \text{CDIV} \cdot \text{OVRSF}}$$

Figure 109. Baud Rate Generator Block Diagram

1M	1	1	1	0	112	84	1	0	115	69	1	0	110	55	1	0	120	12	1	0
1.5M	-	-	-	-	-	-	-	-	110	99	1	0	112	84	1	0	120	18	1	0
2M	-	-	-	-	-	-	-	-	-	-	-	-	1	1	1	0	115	23	1	0
4M	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	115	46	1	0
8M	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	115	92	1	0

Note: 1. This high frequency available through the clock generator requires PLL usage. It is recommended to use it only for high baud rate that can not be achieved using oscillator frequency.

## Receiver

As shown in Figure 110, the receiver is based on a character handler taking care of character integrity check and feeding the reception shift register filling itself a 16-byte data FIFO managed by the FIFO and flow controller.

**Figure 110.** Receiver Block Diagram

## Flow Control

The reception flow can be controlled by hardware using the  $\overline{\text{RTS}}$  pin. The goal of the flow control is to inform the external transmitter when the Rx FIFO is full of a certain amount of data. Thus the transmitter can stop sending characters.  $\overline{\text{RTS}}$  usage and so associated flow control is enabled using RTSEN bit in SFCON.

To support transmitter that has stop latency, a threshold can be programmed to allow characters reception after  $\overline{\text{RTS}}$  has been deasserted. The threshold can be programmed using RTSTH1:0 in SFCON according to Table 242. As soon as enough data has been read from the Rx FIFO,  $\overline{\text{RTS}}$  is asserted again to allow transmitter to continue transmission. To avoid any glitch on  $\overline{\text{RTS}}$  signal, an hysteresis on 1 data is implemented.

Figure 111 shows a reception example using a threshold of 4 data and a host transmitter latency of 3 characters.

**Figure 111.** Reception Flow Control Waveform Example

**Table 242.**  $\overline{\text{RTS}}$  Deassertion Threshold

RTSTH1	RTSTH0	Description
0	0	$\overline{\text{RTS}}$ deasserted when Rx FIFO is full.
0	1	$\overline{\text{RTS}}$ deasserted when 2 data can still be loaded in Rx FIFO.
1	0	$\overline{\text{RTS}}$ deasserted when 4 data can still be loaded in Rx FIFO.
1	1	$\overline{\text{RTS}}$ deasserted when 8 data can still be loaded in Rx FIFO.

## Receiver Errors

There are three kinds of errors that can be set during character reception: the framing error, the parity error, and the overrun error detailed in the following sections.

### Framing Error

A framing error occurs when the stop field of a received character is not at high level. Framing error is reported in FEI flag in SINT. Framing error condition is acknowledged by clearing the FEI flag.

### Parity Error

A parity error occurs when the parity field of a received character does not matches the programmed one in PMOD1:0 bits. Parity error is reported in PEI flag in SINT. Parity error condition is acknowledged by clearing the PEI flag.

### Overrun Error

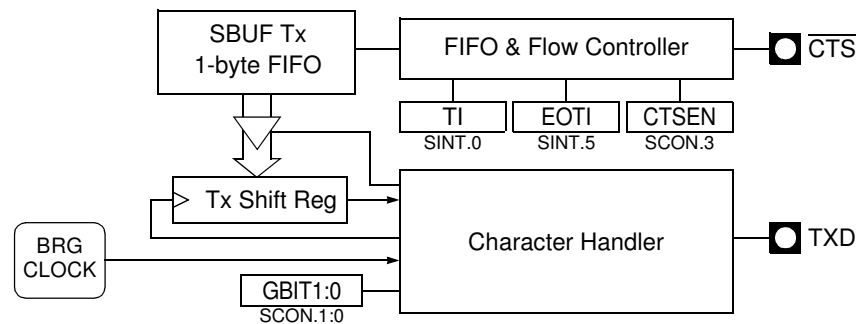

An overrun error occurs when a character is received while the Rx shift register is full (Rx FIFO full). In this case, received character is discarded. Overrun error is reported in OEI flag in SINT. Overrun error condition is acknowledged by clearing the OEI flag.

Note: In case of data burst reception, the error flags report an error within the data burst. It is obvious to discard the whole data burst and to handle the errors by the protocol (retry...).

## Transmitter

As shown in Figure 112, the transmitter is based on a character handler taking care of character transmission and fed by the transmission shift register filled itself by a 1-byte data FIFO managed by the FIFO and flow controller.

**Figure 112.** Transmitter Block Diagram

## Flow Control

The transmission flow can be controlled by hardware using the  $\overline{CTS}$  pin controlled by the external receiver. The goal of the flow control is to stop transmission when the receiver is full of data.  $\overline{CTS}$  usage and so associated flow control is enabled using CTSEN bit in SFCN.

The transmitter stop latency may vary from 0 to a maximum of 1 character, meaning that transmission always stops at the end of the character under transmission if any.

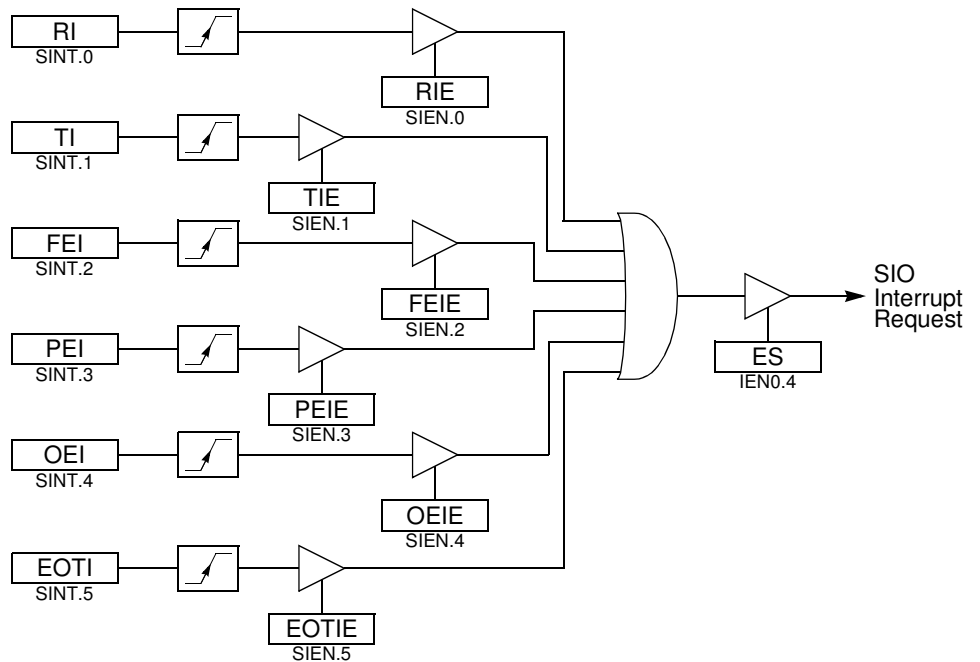

## Interrupts

As shown in Figure 113, the SIO implements five interrupt sources reported in RI, TI, FEI, PEI, OEI and EOTI flags in SINT. These flags are detailed in the previous sections.

These sources are enabled separately using RIE, TIE, FEIE, PEIE, OEIE and EOTIE enable bits respectively in SIEN.

The interrupt request is generated each time an enabled source flag is set, and the global SIO interrupt enable bit is set (ES in IEN0 register).

**Figure 113.** SIO Controller Interrupt System

## Registers

**Table 243.** SCON Register

SCON (0.91h) – SIO Control Register

7	6	5	4	3	2	1	0
SIOEN	PMOD1	PMOD0	PBEN	STOP	DLEN	GBIT1	GBIT0
Bit Number	Bit Mnemonic	Description					
7	SIOEN	<b>SIO Enable Bit</b> Set to enable the Serial Input/Output port. Clear to disable the Serial Input/Output port.					
6-5	PMOD1:0	<b>Parity Mode Bits</b> Refer to Table 238 for information on parity mode					
4	PBEN	<b>Parity Bit Enable Bit</b> Set to enable parity generation according to PMOD1:0 bits. Clear to disable parity generation.					
3	STOP	<b>Stop Bit Number</b> Set to enable generation of 2 stop bits. Clear to enable generation of 1 stop bit.					
2	DLEN	<b>Data Length Bit</b> Set to enable generation of 7 data bits. Clear to enable generation of 8 data bits.					
1-0	GBIT1:0	<b>Guard Bit Number</b> Number of guard bits (from 0 to 3) transmitted after the last stop bit in transmission mode.					

Reset Value = 0000 0000b

## Serial Peripheral Interface

The AT85C51SND3B derivatives implement a Synchronous Peripheral Interface (SPI) allowing full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs.

Features of the SPI module include the following:

- Full-duplex, three-wire synchronous transfers
- Master or Slave operation
- Programmable Master clock rates in master mode
- Serial clock with programmable polarity and phase
- Master Mode fault error flag with MCU interrupt capability

Figure 114 shows a SPI bus configuration using the AT85C51SND3B as master connected to slave peripherals while Figure 115 shows a SPI bus configuration using the AT85C51SND3B as slave of an other master.

The bus is made of three wires connecting all the devices together:

- Master Output Slave Input (MOSI): it is used to transfer data in series from the master to a slave. It is driven by the master.
- Master Input Slave Output (MISO): it is used to transfer data in series from a slave to the master. It is driven by the selected slave.
- Serial Clock (SCK): it is used to synchronize the data transmission both in and out the devices through their MOSI and MISO lines. It is driven by the master for eight clock cycles which allows to exchange one byte on the serial lines.

Each slave peripheral is selected by one Slave Select pin ( $\overline{SS}$ ). If there is only one slave, it may be continuously selected with  $\overline{SS}$  tied to a low level. Otherwise, the AT85C51SND3B may select each device by software through port pins (Pn.x). Special care should be taken not to select 2 slaves at the same time to avoid bus conflicts.

**Figure 114.** Typical Master SPI Bus Configuration

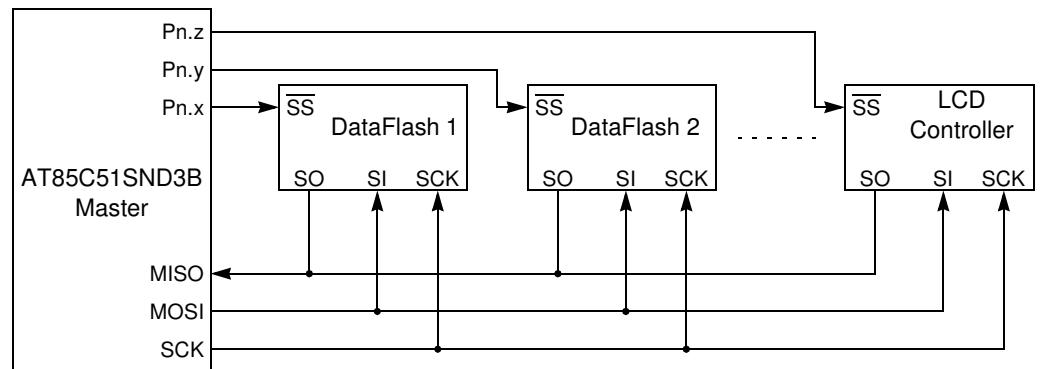

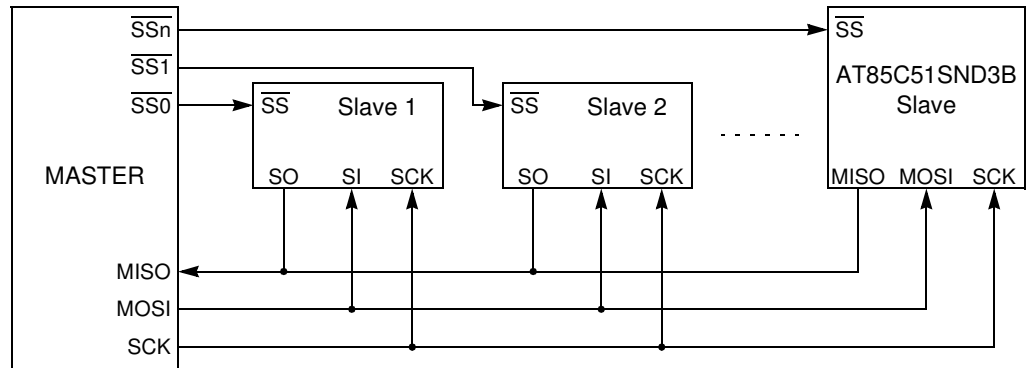

Figure 115. Typical Slave SPI Bus Configuration

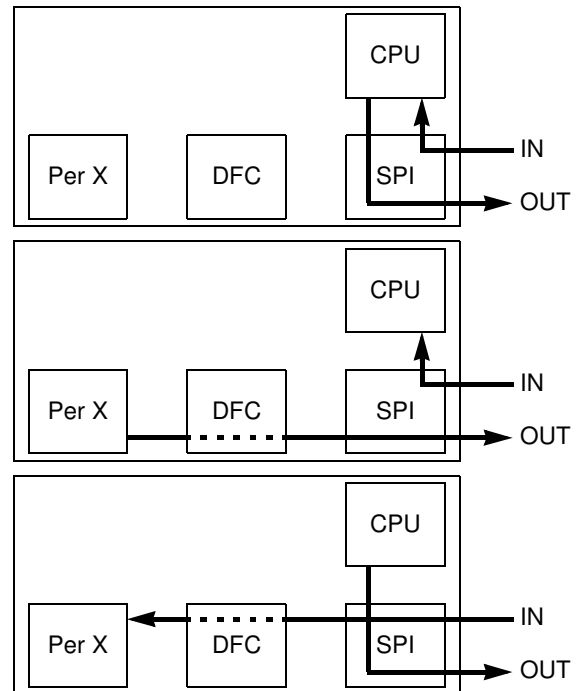

**Description**

The SPI controller interfaces with the C51 core through three special function registers: SPCON, the SPI control register (see Table 252); SPSCR, the SPI status and control register (see Table 253); and SPDAT, the SPI data register (see Table 254). Data flow transfer can be fully handled by the C51 by writing and reading SPDAT or partially by the C51 and the DFC. The SPI controller implements only one DFC channel, meaning only reception flow or transmission flow can be handled by the DFC at a time. The Figure 116 summarizes the different data flow configuration allowed.

Figure 116. SPI Data Flow Configurations

- Data flow is fully handled by the CPU.
- Peripheral X is configured as source and SPI as destination of a DFC channel. CPU is still able to read incoming data (usually status) at its own rate.
- Peripheral X is configured as destination and SPI as source of a DFC channel. CPU is still able to output data (usually status) at its own rate.

**Master Mode**

The SPI operates in master mode when the MSTR bit in SPCON is set.

Note: The SPI Module should be configured as a master before it is enabled (SPEN set). In a system, the master SPI should be configured before the slave SPI device.

Figure 117 shows the SPI block diagram in master mode. Only a master SPI module can initiate transmissions.

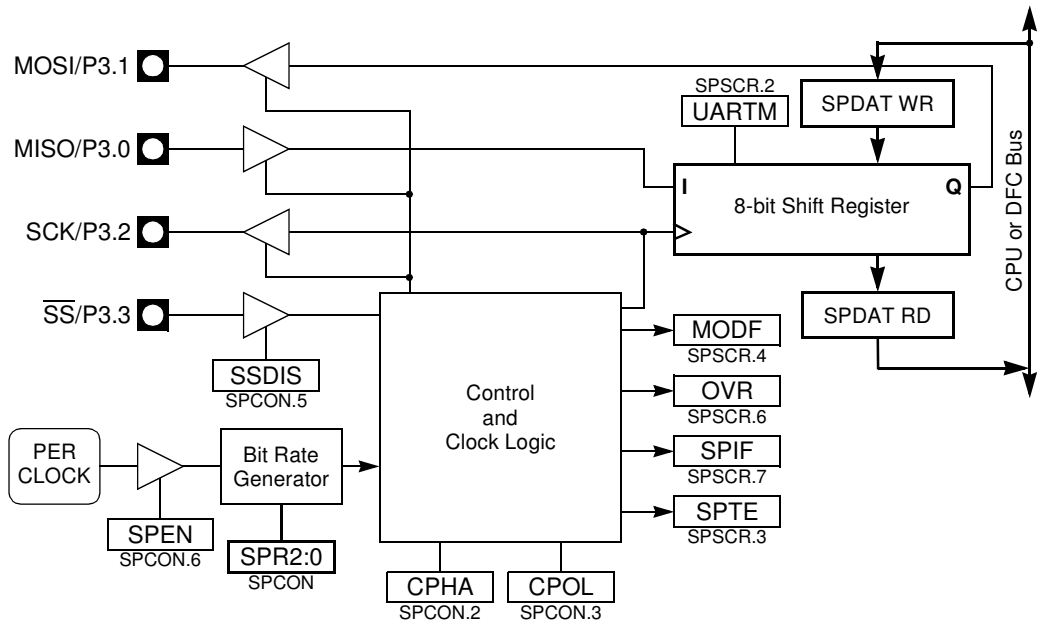

The transmission begins by writing to SPDAT through CPU or DFC. Writing to SPDAT writes to an intermediate register which is automatically loaded to the shift register if no transmission is in progress. Reading SPDAT through CPU or DFC reads an intermediate register updated at the end of each transfer.

The byte begins shifting out on the MOSI pin under the control of the bit rate generator. This generator also controls the shift register of the slave peripheral through the SCK output pin. As the byte shifts out, another byte shifts in from the slave peripheral on the MISO pin. The byte is transmitted most significant bit (MSB) first when UARTM bit in SPCR is cleared or least significant bit (LSB) first when UARTM bit in SPCR is set. The end of transfer is signaled by SPIF being set.

In case SPI is the source of a DFC channel (slave device data read), SPDAT is first loaded with a dummy byte (FFh value) to initiate the transfer. Then transfer continues by transmitting the shift register content which is the last data received.

When the AT85C51SND3B is the only master on the bus, it can be useful not to use  $\overline{SS}$  pin and get it back to I/O functionality. This is achieved by setting SSDIS bit in SPCON.

**Figure 117.** SPI Master Mode Block Diagram

Note: MSTR bit in SPCON is set to select master mode.

## Slave Mode

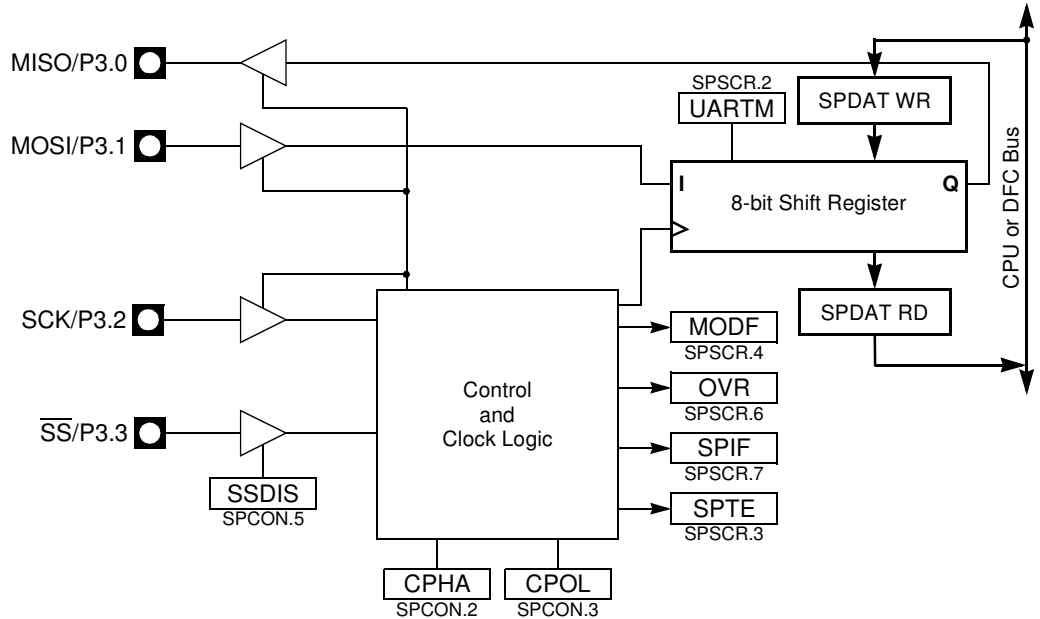

The SPI operates in slave mode when the MSTR bit in SPCON is cleared and data has been loaded in SPDAT.

Note: The SPI Module should be configured as a slave before it is enabled (SPEN set).

Figure 118 shows the SPI block diagram in slave mode. In slave mode, before a data transmission occurs, the  $\overline{SS}$  pin of the slave SPI must be asserted to low level.  $\overline{SS}$  must remain low until the transmission of the byte is complete. In the slave SPI module, data enters the shift register through the MOSI pin under the control of the serial clock provided by the master SPI module on the SCK input pin. When the master starts a transmission, the data in the shift register begins shifting out on the MISO pin. The end of transfer is signaled by SPIF being set.

When the AT85C51SND3B is the only slave on the bus, it can be useful not to use  $\overline{SS}$  pin and get it back to I/O functionality. This is achieved by setting SSDIS bit in SPCON. This bit has no effect when CPHA is cleared (see Section "SS Management", page 228).

**Figure 118.** SPI Slave Mode Block Diagram

Note: MSTR bit in SPCON is cleared to select slave mode.

## Bit Rate

In master mode, the bit rate can be selected from seven predefined bit rates using the SPR2, SPR1 and SPR0 control bits in SPCON according to Table 251. These bit rates are derived from the peripheral clock ( $F_{PER}$ ) issued from the Clock Controller block as detailed in Section "Clock Controller", page 28.

In slave mode, the maximum baud rate allowed on the SCK input is limited to  $F_{OSC} \div 4$ .

**Table 251.** Serial Bit Rates

SPR2	SPR1	SPR0	Bit Rate (kHz) Vs $F_{PER}$ (MHz)							$F_{PER}$ Divider
			6 <sup>(1)</sup>	8 <sup>(1)</sup>	10 <sup>(1)</sup>	12 <sup>(1)(2)</sup>	16 <sup>(2)</sup>	20 <sup>(2)</sup>	24 <sup>(2)</sup>	
0	0	0	3000	4000	5000	6000	8000	10000	12000	2
0	0	1	1500	2000	2500	3000	4000	5000	6000	4
0	1	0	750	1000	1250	1500	2000	2500	3000	8
0	1	1	375	500	625	750	1000	1250	1500	16
1	0	0	187.5	250	312.5	375	500	625	750	32
1	0	1	93.75	125	156.25	187.5	250	312.5	375	64
1	1	0	46.875	62.5	78.125	93.75	125	156.25	187.5	128
1	1	1	-	-	-	-	-	-	-	Reserved

Notes: 1. These frequencies are achieved in X1 mode,  $F_{PER} = F_{OSC} \div 2$ .  
2. These frequencies are achieved in X2 mode,  $F_{PER} = F_{OSC}$ .

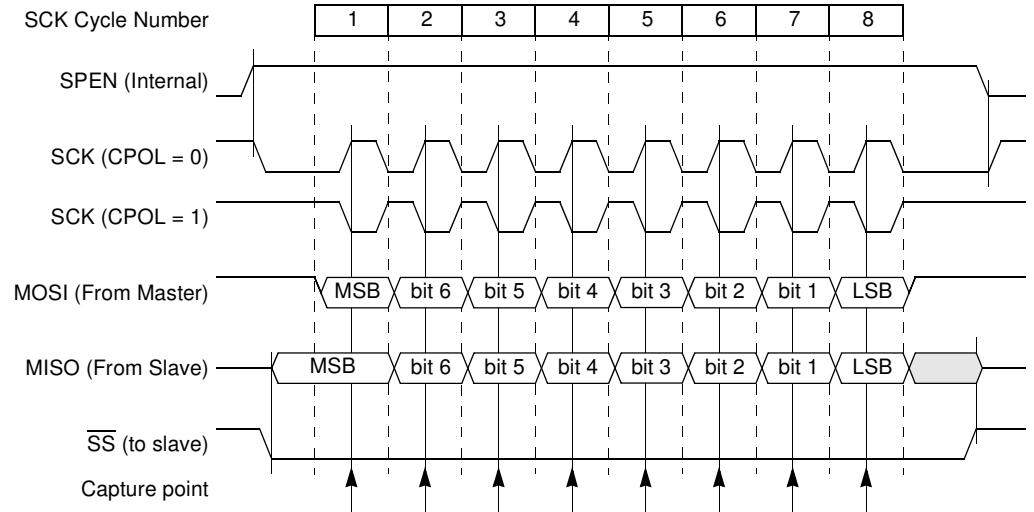

## Data Transfer

The Clock Polarity bit (CPOL in SPCON) defines the default SCK line level in idle state<sup>(1)</sup> while the Clock Phase bit (CPHA in SPCON) defines the edges on which the input data are sampled and the edges on which the output data are shifted (see Figure 119 and Figure 120).

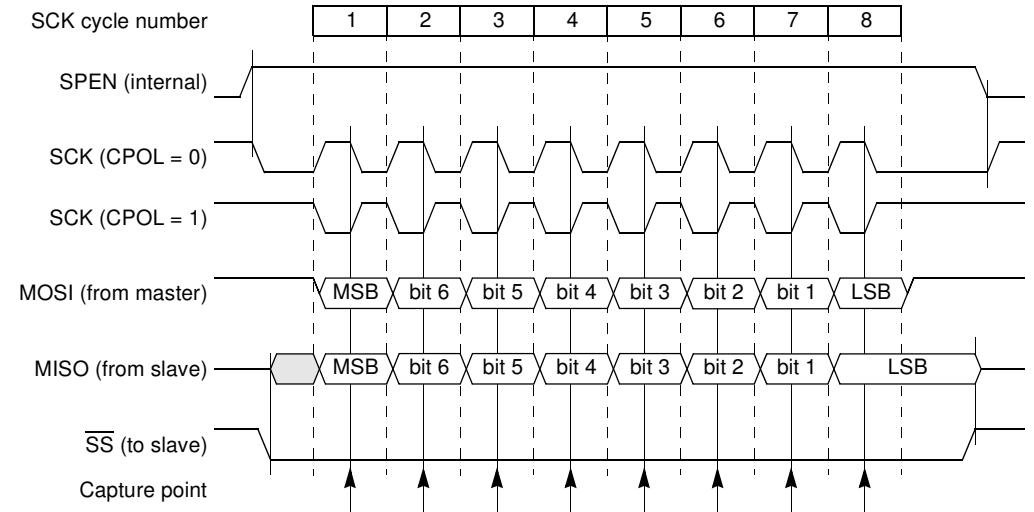

For simplicity, Figure 119 and Figure 120 depict the SPI waveforms in idealized form and do not provide precise timing information. For timing parameters refer to the Section “AC Characteristics”, page 247.

Note: 1. When the peripheral is disabled (SPEN = 0), default SCK line is high level.

**Figure 119.** Data Transmission Format (CPHA = 0, UARTM = 0)

**Figure 120.** Data Transmission Format (CPHA = 1, UARTM = 0)

## SS Management

Figure 119 shows a SPI transmission with CPHA = 0, where the first SCK edge is the MSB capture point. Therefore the slave starts to output its MSB as soon as it is selected:  $\overline{SS}$  asserted to low level.  $\overline{SS}$  must then be de-asserted between each byte transmission (see Figure 121). SPDAT must be loaded with a data before  $\overline{SS}$  is asserted again.

Note: In master mode, SPI transmission with CPHA = 0 is not allowed in case of DFC transfer.

Figure 120 shows a SPI transmission with CPHA = 1, where the first SCK edge is used by the slave as a start of transmission signal. Therefore,  $\overline{SS}$  may remain asserted between each byte transmission (see Figure 121). This format may be preferred in systems having only one master and only one slave driving the MISO data line.

**Figure 121.**  $\overline{SS}$  Timing Diagram

**Queuing Transmission**

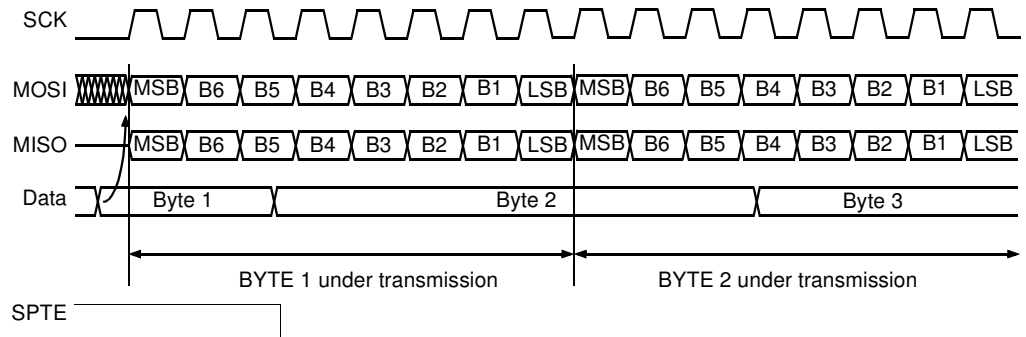

For a SPI configured in master or slave mode, a queued data byte must be transmitted/received immediately after the previous transmission has completed.

When a transmission is in progress a new data can be queued and sent as soon as transmission has been completed. So it is possible to transmit bytes without latency, useful in some applications.

The SPTE bit in SPSCR is set as long as the transmission buffer is free. It means that the user application can write SPDAT with the next data to be transmitted until the SPTE becomes cleared.

Figure 122 shows a queuing transmission in master mode. Once the Byte 1 is ready, it is immediately sent on the bus. Meanwhile another byte is prepared (and the SPTE is cleared), it will be sent at the end of the current transmission. The next data must be ready before the end of the current transmission.

**Figure 122.** Queuing Transmission In Master Mode

In slave mode it is almost the same except it is the external master that starts the transmission. Also, in slave mode, if no new data is ready, the last value received will be the next data byte transmitted.

**Error Conditions**

The following flags in SPSCR register signal the SPI error conditions:

- MODF signals a mode fault condition.
- OVR signals an overrun condition.

*Mode Fault in Master Mode*

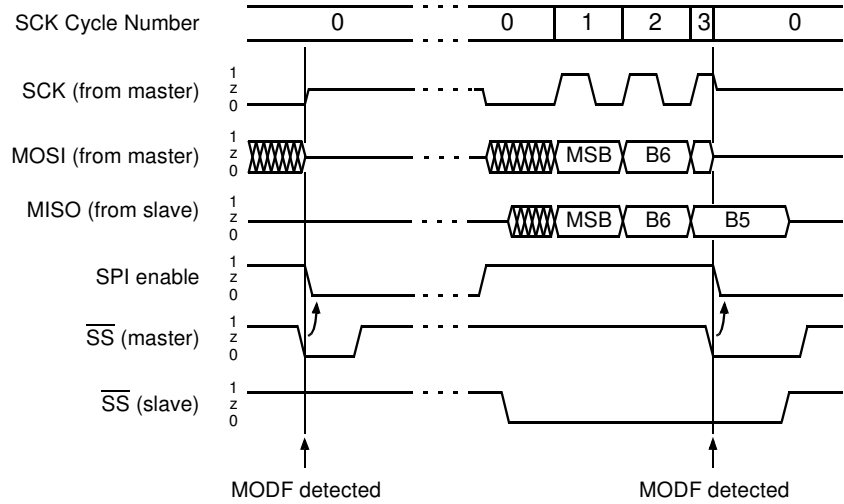

MODF is set to warn that there may be a multi-master conflict for system control. In this case, the SPI controller is affected in the following ways:

- a SPI receiver/error CPU interrupt request is generated
- the SPEN bit in SPCON is cleared. This disables the SPI

- the MSTR bit in SPCON is cleared

Clearing the MODF bit is accomplished by reading SPSCR with MODF bit set, followed by a write to SPCON. SPI controller may be re-enabled (SPEN = 1) after the MODF bit is cleared.

**Figure 123. Mode Fault Conditions in Master Mode (CPHA = 1 / CPOL = 0)**

Note: When  $\overline{SS}$  is disabled (SSDIS set) it is not possible to detect a MODF error in master mode because the SPI is internally unselected and the SS pin is a general purpose I/O.

*Mode Fault in Slave Mode*

MODF error is detected when  $\overline{SS}$  goes high during a transmission. A transmission begins when  $\overline{SS}$  goes low and ends once the incoming SCK goes back to its idle level following the shift of the eighth data bit. A MODF error occurs if a slave is selected ( $\overline{SS}$  is low) and later unselected ( $\overline{SS}$  is high) even if no SCK is sent to that slave.

At any time, a '1' on the  $\overline{SS}$  pin of a slave SPI puts the MISO pin in a high impedance state and internal state counter is cleared. Also, the slave SPI ignores all incoming SCK clocks, even if it was already in the middle of a transmission. A new transmission will be performed as soon as  $\overline{SS}$  pin returns low.

**Figure 124. Mode Fault Conditions in Slave Mode**

Note: when  $\overline{SS}$  is disabled (SSDIS set) it is not possible to detect a MODF error in slave mode because the SPI is internally selected. Also the  $\overline{SS}$  pin becomes a general purpose I/O.

## OverRun Condition

This error means that the speed is not adapted for the running application. An OverRun condition occurs when a byte has been received whereas the previous one has not been read by the application yet. The last byte (which generate the overrun error) does not overwrite the unread data so that it can still be read. Therefore, an overrun error always indicates the loss of data.

## Interrupt

The SPI handles 3 interrupt sources that are the “end of transfer”, the “mode fault” and the “transmit register empty” flags.

As shown in Figure 125, these flags are combined together to appear as a single interrupt source for the C51 core.

The SPIF flag is set at the end of an 8-bit shift in and out and is cleared by reading SPSCR and then reading from or writing to SPDAT.

The MODF flag is set in case of mode fault error and is cleared by reading SPSCR and then writing to SPCON.

The SPTE flag is set when the transmit register is empty and ready to receive new data. When SPTE interrupt source is enabled, SPIF flag does not generate any interrupt.

The SPI interrupt is enabled by setting ESPI bit in IEN1 register. This assumes interrupts are globally enabled by setting EA bit in IEN0 register.

**Figure 125.** SPI Interrupt System

## Registers

**Table 252.** SPCON Register

SPCON (1:91h) – SPI Control Register

7	6	5	4	3	2	1	0
SPR2	SPEN	SSDIS	MSTR	CPOL	CPHA	SPR1	SPR0
Bit Number	Bit Mnemonic	Description					
7	SPR2	<b>SPI Rate Bit 2</b> Refer to Table 251 for bit rate description.					
6	SPEN	<b>SPI Enable Bit</b> Set to enable the SPI interface. Clear to disable the SPI interface.					
5	SSDIS	<b>Slave Select Input Disable Bit</b> Set to disable $\overline{SS}$ in both master and slave modes. In slave mode this bit has no effect if CPHA = 0. Clear to enable $\overline{SS}$ in both master and slave modes.					

Bit Number	Bit Mnemonic	Description
4	MSTR	<b>Master Mode Select</b> Set to select the master mode. Clear to select the slave mode.
3	CPOL	<b>SPI Clock Polarity Bit</b> Set to have the clock output set to high level in idle state. Clear to have the clock output set to low level in idle state.
2	CPHA	<b>SPI Clock Phase Bit</b> Set to have the data sampled when the clock returns to idle state (see CPOL). Clear to have the data sampled when the clock leaves the idle state (see CPOL).
1-0	SPR1:0	<b>SPI Rate Bits 0 and 1</b> Refer to Table 251 for bit rate description.

Reset Value = 0001 0100b

SPSCR (1.92h) – SPI Status and Control Register

7	6	5	4	3	2	1	0
SPIF	-	OVR	MODF	SPTTE	UARTM	SPTTEIE	MODFIE

Bit Number	Bit Mnemonic	Description
7	SPIF	<b>SPI Interrupt Flag</b> Set by hardware when an 8-bit shift is completed. Cleared by hardware to indicate data transfer is in progress or has been acknowledged by a clearing sequence: reading or writing SPDAT after reading SPSCR.
6	-	<b>Reserved</b> The value read from this bit is indeterminate. Do not set this bit.
5	OVR	<b>Overrun Error Flag</b> Set by hardware when a byte is received whereas SPIF is set (the previous received data is not overwritten). Cleared by hardware when reading SPSCR.
4	MODF	<b>Mode Fault Interrupt Flag</b> Set by hardware to indicate that the $\overline{SS}$ pin is in inappropriate logic level. Cleared by hardware when reading SPSCR When MODF error occurred: - In slave mode: SPI interface ignores all transmitted data while $\overline{SS}$ remains high. A new transmission is perform as soon as SS returns low. - In master mode: SPI interface is disabled (SPEN=0, see description for SPEN bit in SPCON register).
3	SPTTE	<b>Serial Peripheral Transmit register Empty Interrupt Flag</b> Set by hardware when transmit register is empty (if needed, SPDAT can be loaded with another data). Cleared by hardware when transmit register is full (no more data should be loaded in SPDAT).
2	UARTM	<b>Serial Peripheral UART mode</b> Set to select UART mode: data is transmitted LSB first. Clear to select SPI mode: data is transmitted MSB first.

Bit Number	Bit Mnemonic	Description
1	SPTEIE	<b>SPTE Interrupt Enable Bit</b> Set to enable SPTE interrupt generation. Clear to disable SPTE interrupt generation.
0	MODFIE	<b>MODF Interrupt Enable Bit</b> Set and cleared by software: - Set to enable MODF interrupt generation - Clear to disable MODF interrupt generation

Reset Value = 0000 1000b

## Display Interface

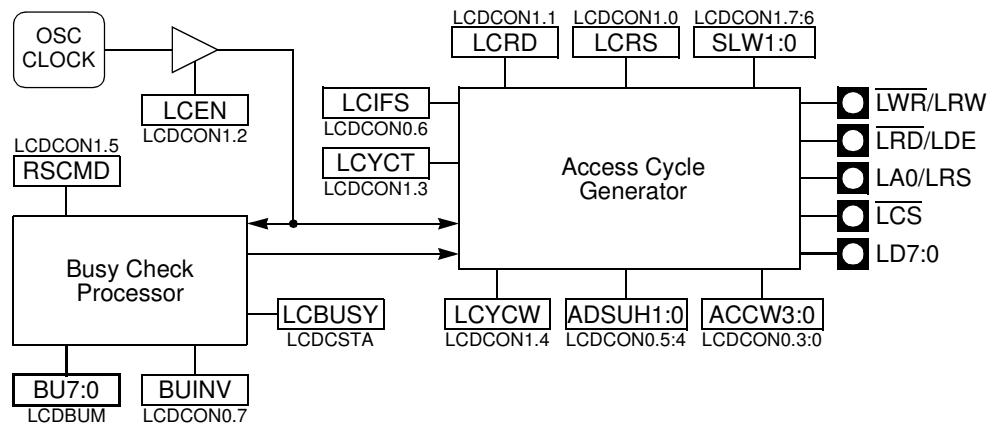

The AT85C51SND3B derivatives implement a display interface allowing glueless direct interfacing (thanks to its highly configurable capability) to almost all of the LCD controllers found in either graphic or text LCD display.

These LCD controllers interface is from either 6800 or 8080 compatible type with some variant in the implementation.

The display interfaces to the C51 core through the following special function registers: LCDCON0, LCDCON1, the LCD control registers (see Table 256 and Table 257); LCDSTA, the LCD status register (see Table 258); LCDBUM, the LCD busy mask register (see Table 259); and LCDDAT, the LCD data register (see Table 260).

As shown in Figure 126, the Display Interface is divided in two major blocks: the Access Cycle Generator which generates read or write cycles to the LCD controller, and the Busy Check Processor which enables automatic busy checking after any read or write cycles.

**Figure 126.** Display Interface Block Diagram

### Configuration

#### Interface Enable

Setting LCEN bit in LCDCON1 enables the display interface. When this bit is cleared, all signals to the controller are switch back to I/O port alternate function. Thus after reset, all signals are set to high level.

#### Interface Selection

The display interface is programmed in 6800 type or 8080 type by setting or clearing the LCIFRS bit LCDCON0. Table 255 shows the pin configuration depending on the interface selected.

**Table 255.** Pin Configuration vs. LCD Controller Interface Type (6800/8080)

Pin Name	8080 Type Controller	6800 Type Controller
$\overline{\text{LWR}}/\text{LRW}$	$\overline{\text{WR}}$	RW
$\overline{\text{LRD}}/\text{LDE}$	$\overline{\text{RD}}$	E
LA0/LRS	A0	RS
$\overline{\text{LCS}}$	$\overline{\text{CS}}$	$\overline{\text{CS}}$
LD7:0	D7:0	D7:0

## Access Cycles

The AT85C51SND3B enables connection of LCD controller with normalized 6800 and 8080 interface as shown in Figure 127 and Figure 128, but also enables connection of LCD controller with non normalized 6800 and 8080 interface as shown in Figure 129 and Figure 130.

This is achieved by setting or clearing CYCT bit in LCDCON1 for selecting non normalized or normalized access type.

**Figure 127.** 6800 Normalized Type Access Cycle

**Figure 128.** 8080 Normalized Type Access Cycle

**Figure 129.** 6800 Special Type Access Cycle

**Figure 130.** 8080 Special Type Access Cycle

## Timings Configuration

As detailed in Figure 131, access cycle timing can be configured to comply with the LCD controller specification. These timing parameters are:

- Address set-up time
- Access width time
- Address hold time
- Sleep Wait time

### Address Set-Up and Hold Time

The address set-up and hold time can be programmed by ADSUH1:0 bits in LCDCON0 from 1 oscillator clock period up to 4 oscillator clock periods. These timing are not dissociated and must be programmed to the highest time value of the set-up and hold time parameters.

### Access Width Time

The access width time can be programmed by ACCW3:0 bits in LCDCON0 from 1 oscillator clock period up to 16 oscillator clock period.

*Sleep Wait Time*

The sleep wait time is the time between two consecutive access cycle. It can be programmed by SLW1:0 bits in LCDCON1 from 1 oscillator clock period up to 4 oscillator clock periods

*Full Access Cycle Time*

The full access cycle time can be computed by adding the address set-up time, the access width time, the address hold time and the sleep wait time. However, some LCD controller may require that the inactive state of the selection signal being equal to the access width time. In such case, LCYCW bit in LCDCON1 must be set.

**Figure 131.** Full Access Cycle Timing

**Automatic Busy Process**

An automatic busy check process can be enabled after any read or write access to the LCD controller to verify this one is ready to execute next instruction.

Busy check configuration uses BUINV bit in LCDCON0, BUM7:0 data in LCDBUM and RSCMD bit in LCDCON1.

RSCMD is used to program the address of the status register (L or H depending on the LCD controller) during the status read cycle.

The busy process performs reads of the LCD controller status register until all relevant busy bits are deasserted (i.e. controller ready). Relevant bits are selected by the BUM7:0 bits set. And busy asserted level is programmed by BUINV, set this bit when busy bit(s) are asserted low, clear it otherwise.

When LCDBUM is reset (i.e. all bits cleared), no busy check is performed.

*Busy Report*

The busy state report is done by the LCBUSY flag in LCDSTA. LCBUSY is set at the beginning of any read or write cycles and cleared at the end of any access cycle (after the sleep wait time) when the automatic busy check process is disabled or at the end of the first LCD controller ready status read cycle (after the sleep wait time) when the automatic busy check process is enabled.

LCBUSY flag must be checked before performing any read or write cycle to the LCD controller.

**Read / Write Operation**

LCD controllers have two registers, the display data register and instruction/status register. To determine which register will be accessed, LCRS bit in LCDCON1 must be configured according to the LCD controller.

*Write Access*

While the display interface is enabled, writing a data to LCDDAT launches a write cycle to the LCD controller according to the programmed configuration.

*Read Access*

While the display interface is enabled, setting LCRD bit in LCDCON1 launches a read cycle to the LCD controller according to the programmed configuration. At the end of the read cycle, including busy time, data can be retrieved by reading LCDAT. Reading LCDAT automatically relaunches a new read cycle to the LCD controller allowing continuous read of data.

Registers

Reset Value= 0000 0000b

## Keyboard Interface

The AT85C51SND3B derivatives implement a keyboard interface allowing the connection of a 4 x n matrix keyboard. It is based on 4 inputs with programmable interrupt capability on both high or low level. These inputs are available as alternate function of P1.3:0 and allow exit from idle and power down modes.

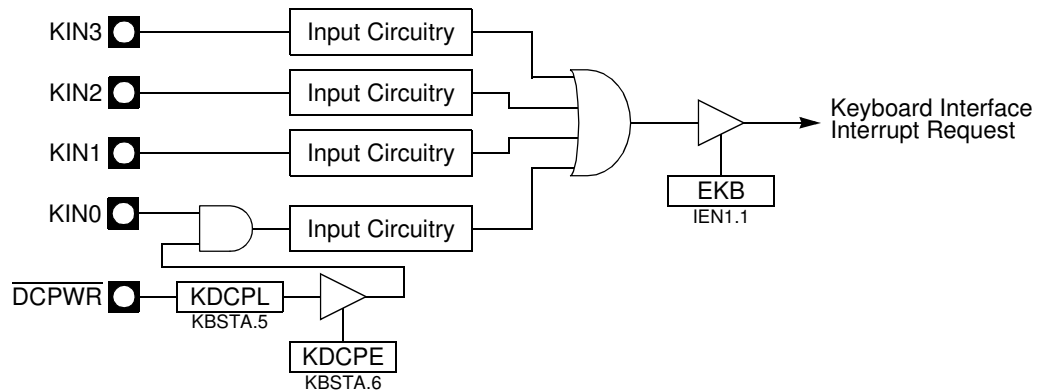

### Description

The keyboard interfaces with the C51 core through 2 special function registers: KBCON, the keyboard control register (see Table 261); and KBSTA, the keyboard control and status register (see Table 262).

The keyboard inputs are considered as 4 independent interrupt sources sharing the same interrupt vector. An interrupt enable bit (EKB in IEN1 register) allows global enable or disable of the keyboard interrupt (see Figure 132). As detailed in Figure 133 each keyboard input has the capability to detect a programmable level according to KINL3:0 bit value in KBCON register. Level detection is then reported in interrupt flags KINF3:0 in KBSTA register.

A keyboard interrupt is requested each time one of the four flags is set, i.e. the input level matches the programmed one. Each of these four flags can be masked by software using KINM3:0 bits in KBCON register and is cleared by reading KBSTA register. This structure allows keyboard arrangement from 1 by n to 4 by n matrix and allows usage of KIN inputs for any other purposes.

**Figure 132.** Keyboard Interface Block Diagram

**Figure 133.** Keyboard Input Circuitry

### Power Reduction Modes

KIN3:0 inputs allow exit from idle and power-down modes as detailed in Section "Power Reduction Mode", page 21. To enable power-down mode exit, KPDE bit in KBSTA register must be set.

Due to the asynchronous keypad detection in power down mode (all clocks are stopped), exit may happen on parasitic key press. In this case, no key is detected and software returns to power down again.

Registers

**Table 261.** KBCON Register

KBCON (0.A3h) – Keyboard Control Register

## Document Revision History

**Changes from  
Rev. A - 03/06 to  
Rev. B - 04/06**

1. Update to "Electrical Characteristics" on page 242.
2. Update to product features on page 1.

**Changes from  
Rev. B - 04/06 to  
Rev. C - 10/06**

1. Added BGA pinout drawing on page 7.
2. PSI Timings updated.
3. Part numbers changed.

**Changes from  
Rev. C - 10/06 to  
Rev. D - 01/07**

1. Correction to ordering information.
