# 40V, High-Performance, Synchronous Buck Controller 

General Description

The MAX15046 synchronous step-down controller operates from a 4.5 V to 40 V input voltage range and generates an adjustable output voltage from $85 \%$ of the input voltage down to 0.6 V , supporting loads up to 25 A . The device allows monotonic startup into a prebiased bus without discharging the output and features adaptive internal digital soft-start.
The MAX15046 offers the ability to adjust the switching frequency from 100 kHz to 1 MHz with an external resistor. The MAX15046's adaptive synchronous rectification eliminates the need for an external freewheeling Schottky diode. The device also utilizes the external low-side MOSFET's on-resistance as a current-sense element, eliminating the need for a current-sense resistor. This protects the DC-DC components from damage during output overloaded conditions or output shortcircuit faults without requiring a current-sense resistor. Hiccup-mode current limit reduces power dissipation during short-circuit conditions. The MAX15046 includes a power-good output and an enable input with precise turn-on/turn-off threshold, which can be used for input supply monitoring and for power sequencing.
Additional protection features include sink-mode current limit, and thermal shutdown. Sink-mode current limit prevents reverse inductor current from reaching dangerous levels when the device is sinking current from the output.

The MAX15046 is available in a 16 -pin QSOP or 16-pin QSOP-EP package and operates over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ temperature range.

Pin Configurations appear at end of data sheet.

Features

- Input Voltage Ranges from 4.5 V to 40 V or 5 V $\pm 10 \%$
- Adjustable Outputs from $0.85 \times$ VIN Down to 0.6 V
- Adjustable Switching Frequency (100kHz to 1MHz) with $\pm 10 \%$ ( 1 MHz ) Accuracy
- Adaptive Internal Digital Soft-Start
- Up to 25A Output Capability
- Cycle-by-Cycle Valley-Mode Current Limit with Adjustable, Temperature-Compensated Threshold ( 30 mV to 300 mV )
- Monotonic Startup into Prebiased Output
- $\pm 1 \%$ Accurate Voltage Reference
- 3A-Peak Gate Drivers
- Hiccup-Mode Short-Circuit Protection (PatentPending Architecture)
- Overtemperature Shutdown
- Power-Good (PGOOD) Output and Enable Input (EN) with $\pm 5 \%$ Accurate Threshold
- Thermally Enhanced 16-Pin QSOP Package

Applications
Industrial Power Supplies (PLC, Industrial Computers, Fieldbus Components, Fieldbus Couplers)
Telecom Power Supplies
Base Stations

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to http://www.maxim-ic.com/thermal-tutorial.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## 40V, High-Performance, Synchronous Buck Controller

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | IN | Regulator Input. Connect to the input rail of the buck converter. Bypass IN to PGND with a 100 nF minimum ceramic capacitor. When operating in the $5 \mathrm{~V} \pm 10 \%$ range, connect IN to Vcc. |
| 2 | Vcc | 5.25V Linear Regulator Output. Bypass $V_{C C}$ to PGND with a ceramic capacitor of at least $4.7 \mu \mathrm{~F}$ when Vcc supplies MOSFET gate-driver current at DRV or $2.2 \mu \mathrm{~F}$ when $\mathrm{V}_{\mathrm{Cc}}$ is not used to power DRV. |
| 3 | PGOOD | Open-Drain Power-Good Output. Pull up PGOOD to an external power supply or output with an external resistor. |
| 4 | EN | Active-High Enable Input. Pull EN to GND to disable the buck converter output. Connect to VCC for always-on operation. EN can be used for power sequencing and as a UVLO adjustment input. |
| 5 | LIM | Current-Limit Input. Connect a resistor from LIM to GND to program the current-limit threshold from $30 \mathrm{mV}($ RLIM $=6 \mathrm{k} \Omega)$ to $300 \mathrm{mV}($ RLIM $=60 \mathrm{k} \Omega)$. |
| 6 | COMP | Error-Amplifier Output. Connect compensation network from COMP to FB or from COMP to GND. |
| 7 | FB | Feedback Input (Inverting Input of Error Amplifier). Connect FB to a resistive divider between the buck converter output and GND to adjust the output voltage from 0.6 V up to $0.85 \times \mathrm{IN}$. |
| 8 | RT | Oscillator-Timing Resistor Input. Connect a resistor from RT to GND to set the oscillator frequency from 100 kHz to 1 MHz . |
| 9 | GND | Analog Ground. Connect PGND and AGND together at a single point. |
| 10 | PGND | Power Ground. Use PGND as a return path for the low-side MOSFET gate driver. |
| 11 | DRV | Gate-Driver Supply Voltage. DRV is internally connected to the low-side driver supply. Bypass DRV to PGND with a $2.2 \mu \mathrm{~F}$ minimum ceramic capacitor (see the Typical Application Circuits). |
| 12 | DL | Low-Side External MOSFET Gate-Driver Output. DL swings from DRV to PGND. |
| 13 | BST | Boost Flying Capacitor Connection. Internally connected to the high-side driver supply. Connect a ceramic capacitor of at least 100 nF between BST and LX and a diode between BST and DRV for the high-side MOSFET gate-driver supply. |
| 14 | LX | Inductor Connection. Also serves as a return terminal for the high-side MOSFET driver current. Connect LX to the switching side of the inductor. |
| 15 | DH | High-Side External MOSFET Gate-Driver Output. DH swings from BST to LX. |
| 16 | CSP | Current-Sense Positive Input. Connect to the drain of low-side MOSFET with Kelvin connection. |
| - | EP | Exposed Pad. EP is internally connected to ground. Connect EP to a large copper ground plane to maximize thermal performance. |

## 40V, High-Performance, Synchronous Buck Controller

Functional Diagram

# 40V, High-Performance, Synchronous Buck Controller 

___Detailed Description
The MAX15046 synchronous step-down controller operates from a 4.5 V to 40 V input-voltage range and generates an adjustable output voltage from $85 \%$ of the inputvoltage down to 0.6 V while supporting loads up to 25 A . As long as the device supply voltage is within 5.0 V to 5.5 V , the input power bus $(\mathrm{VIN})$ can be as low as 3.3 V .

The MAX15046 offers adjustable switching frequency from 100 kHz to 1 MHz with an external resistor. The adjustable switching frequency provides design flexibility in selecting passive components. The MAX15046 adopts an adaptive synchronous rectification to eliminate external freewheeling Schottky diodes and improve efficiency. The device utilizes the on-resistance of the external low-side MOSFET as a current-sense element. The current-limit threshold voltage is resistor-adjustable from 30 mV to 300 mV and is temperature-compensated, so that the effects of the MOSFET RDS(ON) variation over temperature are reduced. This current-sensing scheme protects the external components from damage during output overloaded conditions or output shortcircuit faults without requiring a current-sense resistor. Hiccup-mode current limit reduces power dissipation during short-circuit conditions. The MAX15046 includes a power-good output and an enable input with precise turn-on/-off threshold to be used for monitoring and for power sequencing.
The MAX15046 features internal digital soft-start that allows prebias startup without discharging the output. The digital soft-start function employs sink current limiting to prevent the regulator from sinking excessive current when the prebias voltage exceeds the programmed steadystate regulation level. The digital soft-start feature prevents the synchronous rectifier MOSFET and the body diode of the high-side MOSFET from experiencing dangerous levels of current while the regulator is sinking current from the output. The MAX15046 shuts down at a $+150^{\circ} \mathrm{C}$ junction temperature to prevent damage to the device.

DC-DC PWM Controller
The MAX15046 step-down controller uses a PWM volt-age-mode control scheme (see the Functional Diagram). Control-loop compensation is external for providing maximum flexibility in choosing the operating frequency and output LC filter components. An internal transconductance error amplifier produces an integrated error voltage at COMP that helps to provide higher DC accuracy. The voltage at COMP sets the duty cycle using a PWM
comparator and a ramp generator. On the rising edge of an internal clock, the high-side n-channel MOSFET turns on and remains on until either the appropriate duty cycle or the maximum duty cycle is reached. During the on-time of the high-side MOSFET, the inductor current ramps up. During the second-half of the switching cycle, the high-side MOSFET turns off and the low-side n-channel MOSFET turns on. The inductor releases the stored energy as the inductor current ramps down, providing current to the output. Under overload conditions, when the inductor current exceeds the selected valley current-limit threshold (see the Current-Limit Circuit (LIM) section), the high-side MOSFET does not turn on at the subsequent clock rising edge and the low-side MOSFET remains on to let the inductor current ramp down.

Internal 5.25V Linear Regulator An internal linear regulator (VCC) provides a 5.25 V nominal supply to power the internal functions and to drive the low-side MOSFET. Connect IN and VCC together when using an external $5 \mathrm{~V} \pm 10 \%$ power supply. The maximum regulator input voltage $\left(\mathrm{V}_{\mathrm{IN}}\right)$ is 40 V . Bypass IN to GND with a $1 \mu \mathrm{~F}$ ceramic capacitor. Bypass the output of the linear regulator (VCC) with a $4.7 \mu \mathrm{~F}$ ceramic capacitor to GND. The VCC dropout voltage is typically 180 mV . When VIN is higher than 5.5 V , VVCC is typically 5.25 V . The MAX15046 also employs an undervoltage lockout circuit that disables the internal linear regulator when VVCC falls below 3.6 V (typical). The 400 mV UVLO hysteresis prevents chattering on power-up/power-down.

## MOSFET Gate Drivers (DH, DL)

DH and DL are optimized for driving large-size n-channel power MOSFETs. Under normal operating conditions and after startup, the DL low-side drive waveform is always the complement of the DH high-side drive waveform, with controlled dead time to prevent crossconduction or "shoot-through." An adaptive dead-time circuit monitors the DH and DL outputs and prevents the opposite-side MOSFET from turning on until the MOSFET is fully off. Thus, the circuit allows the high-side driver to turn on only when the DL gate driver has turned off preventing the low side (DL) from turning on until the DH gate driver has turned off.
The adaptive driver dead time allows operation without shoot-through with a wide range of MOSFETs, minimizing delays and maintaining efficiency. There must be a low-resistance, low-inductance path from DL and DH to the MOSFET gates for the adaptive dead-time circuits

## 40V, High-Performance, Synchronous Buck Controller

to function properly. The stray impedance in the gate discharge path can cause the sense circuitry to interpret the MOSFET gate as "off" while the VGS of the MOSFET is still high. To minimize stray impedance, use very short, wide traces.
Synchronous rectification reduces conduction losses in the rectifier by replacing the normal low-side Schottky catch diode with a low-resistance MOSFET switch. The MAX15046 features a robust internal pulldown transistor with a typical $1 \Omega \operatorname{RDS}(\mathrm{ON})$ to drive DL low. This low onresistance prevents DL from being pulled up during the fast rise time of the LX node, due to capacitive coupling from the drain to the gate of the low-side synchronous rectifier MOSFET.

High-Side Gate-Drive Supply (BST) An external Schottky diode between BST and DH is required to boost the gate voltage above LX providing the necessary gate-to-source voltage to turn on the highside MOSFET. The boost capacitor connected between BST and LX holds up the voltage across the floating gate driver during the high-side MOSFET on-time.

The charge lost in the boost capacitor for delivering the gate charge is replenished when the high-side MOSFET turns off and the LX node goes to ground. When LX is low, the external diode between VDRV and BST recharges the boost capacitor. See the Boost Capacitor and Diode Selection section in the Applications Information to choose the right boost capacitor and diode.

Enable Input (EN), Soft-Start, and Soft-Stop Drive EN high to turn on the MAX15046. A soft-start sequence starts to increase (step-wise) the reference voltage of the error amplifier. The duration of the softstart ramp is 2048 switching cycles and the resolution is 1/64th of the steady-state regulation voltage allowing a smooth increase of the output voltage. A logic-low on EN initiates a soft-stop sequence by stepping down the reference voltage of the error amplifier. After the soft-stop sequence is completed, the MOSFET drivers are both turned off. See Figure 1.
Connect EN to VCC for always-on operation. Owing to the accurate turn-on/-off thresholds, EN can be used as a UVLO adjustment input, and for power sequencing together with the PGOOD outputs.

Figure 1. Power On-Off Sequencing

## 40V, High-Performance, Synchronous Buck Controller

When the valley current limit is reached during soft-start, the MAX15046 regulates to the output impedance times the limited inductor current and turns off after 4096 clock cycles. When starting up into a large capacitive load (for example), the inrush current will not exceed the currentlimit value. If the soft-start is not completed before 4096 clock cycles, the device turns off. The device remains off for 8192 clock cycles before trying to soft-start again. This implementation allows the soft-start time to be automatically adapted to the time necessary to keep the inductor current below the limit while charging the output capacitor.

## Power-Good Output (PGOOD)

The MAX15046 includes a power-good comparator to monitor the output voltage and detect the power-good threshold, fixed at $93 \%$ of the nominal FB voltage. The open-drain PGOOD output requires an external pullup resistor. PGOOD sinks up to 2 mA of current while low.
PGOOD goes high (high-Z) when the regulator output increases above $93 \%$ of the designed nominal regulated voltage. PGOOD goes low when the regulator output voltage drops to below $90 \%$ of the nominal regulated voltage. PGOOD asserts low during the hiccup timeout period.

Startup into a Prebiased Output When the MAX15046 starts into a prebiased output, DH and DL are off so that the converter does not sink current from the output. DH and DL do not start switching until the PWM comparator commands the first PWM pulse. The first PWM pulse occurs when the ramping reference voltage increases above the FB voltage.
When the output voltage is biased above the output set point, the controller tries to pull the output down to the set point once the internal soft-start is complete. This pulldown is controlled by the sink current limit, which is slowly increased to its normal value to minimize output undershoot.

## Current-Limit Circuit (LIM)

The current-limit circuit employs a 'valley' and sink current-sensing algorithm that uses the on-resistance of the low-side MOSFET as a current-sensing element, to eliminate costly sense resistors. The current-limit circuit is also temperature compensated to track the on-resistance variation of the MOSFET overtemperature. The current limit is adjustable with an external resistor at LIM and accommodates MOSFETs with a wide range of on-resistance characteristics (see the Setting the Valley Current Limit section). The adjustment range is from 0.3 V
to 3 V for the valley current limit, corresponding to resistor values of $6 \mathrm{k} \Omega$ to $60 \mathrm{k} \Omega$. The valley current-limit threshold across the low-side MOSFET is precisely $1 / 10$ th of the voltage at LIM, while the sink current-limit threshold is 1/20th of the voltage at LIM.
Valley current limit acts when the inductor current flows towards the load, and CSP is more negative than PGND during the low-side MOSFET on-time. If the magnitude of the current-sense signal exceeds the valley current-limit threshold at the end of the low-side MOSFET on-time, the MAX15046 does not initiate a new PWM cycle and lets the inductor current decay in the next cycle. The controller also 'rolls back' the internal reference voltage so that the controller finds a regulation point determined by the current-limit value and the resistance of the short. In this manner, the controller acts as a constant current source. This method greatly reduces inductor ripple current during the short event, which reduces inductor sizing restrictions and reduces the possibility for audible noise. After 4096 clock cycles, the device goes into hiccup mode. Once the short is removed, the internal reference voltage soft-starts back up to the normal reference voltage and regulation continues.
Sink current limit is implemented by monitoring the voltage drop across the low-side MOSFET when CSP is more positive than PGND. When the voltage drop across the low-side MOSFET exceeds $1 / 20$ th of the voltage at LIM at any time during the low-side MOSFET on-time, the low-side MOSFET turns off and the inductor current flows from the output through the body diode of the high-side MOSFET. When the sink current limit activates, the DH/ DL switching sequence is no longer complementary and both MOSFETs are turned off.
Carefully observe the PCB layout guidelines to ensure that noise and DC errors do not corrupt the currentsense signals at CSP and PGND. Mount the MAX15046 close to the low-side MOSFET with short, direct traces making a Kelvin-sense connection so that trace resistance does not add to RDS(ON) of the low-side MOSFET.

## Hiccup Mode Overcurrent Protection

Hiccup mode overcurrent protection reduces power dissipation during prolonged short-circuit or severe overload conditions. An internal 3-bit counter counts up on each switching cycle when the valley current-limit threshold is reached. The counter counts down on each switching cycle when the threshold is not reached, and stops at zero (000). When the current-limit condition persists and the counter reaches 111 (= 7 events), the

## 40V, High-Performance, Synchronous Buck Controller

MAX15046 stops both DL and DH drivers and waits for 4096 switching cycles (hiccup timeout delay) before attempting a new soft-start sequence. The hiccup-mode protection remains active during the soft-start time.

Undervoltage Lockout The MAX15046 provides an internal undervoltage lockout (UVLO) circuit to monitor the voltage on VCC. The UVLO circuit prevents the MAX15046 from operating when VCC is lower than VUVLO. The UVLO threshold is 4 V , with 400 mV hysteresis to prevent chattering on the rising/falling edge of the supply voltage. DL and DH stay low to inhibit switching when the device is in undervoltage lockout.

## Thermal-Overload Protection

Thermal-overload protection limits total power dissipation in the MAX15046. When the junction temperature of the device exceeds $+150^{\circ} \mathrm{C}$, an on-chip thermal sensor shuts down the device, forcing DL and DH low, which allows the device to cool. The thermal sensor turns the device on again after the junction temperature cools by $20^{\circ} \mathrm{C}$. The regulator shuts down and soft-start resets during thermal shutdown. Power dissipation in the LDO regulator and excessive driving losses at DH/DL trigger thermal-overload protection. Carefully evaluate the total power dissipation (see the Power Dissipation section) to avoid unwanted triggering of the thermal-overload protection in normal operation.

## Applications Information

## Effective Input-Voltage Range

The MAX15046 operates from 4.5V to 40V input supplies and regulates output down to 0.6 V . The minimum voltage conversion ratio (VOUT/VIN) is limited by the minimum controllable on-time. For proper fixed-frequency PWM operation, the voltage conversion ratio must obey the following condition:

$$
\frac{V_{\mathrm{OUT}}}{V_{\mathrm{IN}}}>\mathrm{t}_{\mathrm{ON}(\mathrm{MIN})} \times \mathrm{f}_{\mathrm{SW}}
$$

where tON(MIN) is 125ns and fSW is the switching frequency in Hertz. Pulse skipping occurs to decrease the effective duty cycle when the desired voltage conversion does not meet the above condition. Decrease the switching frequency or lower the input voltage VIN to avoid pulse skipping.

The maximum voltage conversion ratio is limited by the maximum duty cycle (Dmax):

$$
\frac{V_{\mathrm{OUT}}}{V_{\mathrm{IN}}}<\mathrm{D}_{\max }-\frac{\mathrm{D}_{\max } \times \mathrm{V}_{\mathrm{DROP} 2}+\left(1-\mathrm{D}_{\max }\right) \times \mathrm{V}_{\mathrm{DROP} 1}}{\mathrm{~V}_{\mathrm{IN}}}
$$

where VDROP1 is the sum of the parasitic voltage drops in the inductor discharge path, including synchronous rectifier, inductor, and PCB resistance. VDROP2 is the sum of the resistance in the charging path, including high-side switch, inductor, and PCB resistance. In practice, provide adequate margin to the above conditions for good load-transient response.

## Setting the Output Voltage

Set the MAX15046 output voltage by connecting a resistive divider from the output to FB to GND (Figure 2). Select R2 from between $4 \mathrm{k} \Omega$ and $16 \mathrm{k} \Omega$. Calculate R1 with the following equation:

$$
\mathrm{R}_{1}=\mathrm{R}_{2}\left[\left(\frac{\mathrm{~V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{FB}}}\right)-1\right]
$$

where $\mathrm{V}_{\mathrm{FB}}=0.59 \mathrm{~V}$ (see the Electrical Characteristics table) and VOUT can range from 0.6 V to ( $0.85 \times$ VIN).
Resistor R1 also plays a role in the design of the Type III compensation network. Review the values of R1 and R2 when using a Type III compensation network (see the Type III Compensation Network (Figure 4) section).

Figure 2. Adjustable Output Voltage

# 40V, High-Performance, Synchronous Buck Controller 

An Setting the Switching Frequency switching frequency (fsw). The relationship between fsw and RRT is:

$$
R_{R T}=\frac{17.3 \times 10^{9}}{f_{S W}+\left(1 \times 10^{-7}\right) \times\left(f_{S W}{ }^{2}\right)}
$$

where fsw is in kHz and RRT is in $\mathrm{k} \Omega$. For example, a 300 kHz switching frequency is set with RRT $=49.9 \mathrm{k} \Omega$. Higher frequencies allow designs with lower inductor values and less output capacitance. Peak currents and I2R losses are lower at higher switching frequencies, but core losses, gate-charge currents, and switching losses increase.

## Inductor Selection

Three key inductor parameters must be specified for operation with the MAX15046: inductance value (L), inductor saturation current (ISAT), and DC resistance (RDC). To determine the inductance, select the ratio of inductor peak-to-peak AC current to DC average current (LIR) first. For LIR values that are too high, the RMS currents are high, and therefore ${ }^{2} \mathrm{R}$ losses are high. Use high-valued inductors to achieve low LIR values. Typically, inductor resistance is proportional to inductance for a given package type, which again makes I2R losses high for very low LIR values. A good compromise between size and loss is a $30 \%$ peak-to-peak ripple current to average-current ratio (LIR = 0.3). The switching frequency, input voltage, output voltage, and selected LIR determine the inductor value as follows:

$$
L=\frac{V_{\text {OUT }}\left(V_{\text {IN }}-V_{\text {OUT }}\right)}{V_{\text {IN }} \times f_{\text {SW }} \times I_{\text {OUT }} \times \mathrm{LIR}}
$$

where VIN, Vout, and Iout are typical values. The switching frequency is set by RT (see Setting the Switching Frequency section). The exact inductor value is not critical and can be adjusted to make trade-offs among size, cost, and efficiency. Lower inductor values minimize size and cost, but also improve transient response and reduce efficiency due to higher peak currents. On the other hand, higher inductance increases efficiency by reducing the RMS current.
Find a low-loss inductor with the lowest possible DC resistance that fits in the allotted dimensions. The
saturation current rating (ISAT) must be high enough to ensure that saturation cannot occur below the maximum current-limit value (ICL(MAX)), given the tolerance of the on-resistance of the low-side MOSFET and of the LIM reference current (ILIM). Combining these conditions, select an inductor with a saturation current (ISAT) of:

$$
\mathrm{I}_{\mathrm{SAT}} \geq 1.35 \times \mathrm{I}_{\mathrm{CL}(\mathrm{TYP})}
$$

where ICL(TYP) is the typical current-limit set point. The factor 1.35 includes RDS(ON) variation of $25 \%$ and $10 \%$ for the LIM reference current error. A variety of inductors from different manufacturers are available to meet this requirement (for example, Vishay IHLP-4040DZ-1-5 and other inductors from the same series).

Setting the Valley Current Limit The minimum current-limit threshold must be high enough to support the maximum expected load current with the worst-case low-side MOSFET on-resistance value as the RDS(ON) of the low-side MOSFET is used as the currentsense element. The inductor's valley current occurs at $\operatorname{ILOAD}(\mathrm{MAX})$ minus one half of the ripple current. The minimum value of the current-limit threshold voltage (VITH) must be higher than the voltage on the low-side MOSFET during the ripple-current valley,

$$
V_{I T H}>R_{D S(O N, M A X)} \times \operatorname{ILOAD}(M A X) \times\left(1-\frac{\mathrm{LIR}}{2}\right)
$$

where $\operatorname{RDS}(\mathrm{ON}, \mathrm{MAX})$ in $\Omega$ is the maximum on-resistance of the low-side MOSFET at maximum load current $\operatorname{LOAD}($ MAX ) and is calculated from the following equation:

$$
\mathrm{R}_{\mathrm{DS}(\mathrm{ON}, \mathrm{MAX})}=\mathrm{R}_{\mathrm{DS}(\mathrm{ON})} \times\left[1+\mathrm{TC}_{\mathrm{MOSFET}} \times\left(\mathrm{T}_{\mathrm{MAX}}-\mathrm{T}_{\mathrm{AMB}}\right)\right]
$$

where $\operatorname{RDS}(\mathrm{ON}$ ) (in $\Omega$ is the on-resistance of the lowside MOSFET at ambient temperature TAMB (in degrees Celsius), TCMOSFET is the temperature coefficient of the low-side MOSFET in ppm $/{ }^{\circ} \mathrm{C}$, and $\operatorname{TMAX}$ (in degrees Celsius) is the temperature at maximum load current ILOAD(MAX). Obtain the RDS(ON) and TCMOSFET from the MOSFET data sheet.

## 40V, High-Performance, Synchronous Buck Controller

Connect an external resistor (RLIM) from LIM to GND to adjust the current-limit threshold, which is temper-ature-compensated with a temperature coefficient of -2300ppm $/{ }^{\circ} \mathrm{C}$. The relationship between the current-limit threshold (VITH) and RLIM is:

$$
R_{\text {LIM }}=\frac{10 \times V_{\text {ITH }}}{50 \times 10^{-6} \times\left[1+2300 \times\left(T_{M A X}-T_{\text {AMB }}\right)\right]}
$$

where RLIM is in $\Omega$, VITH is in $V$, TMAX and TAMB are in ${ }^{\circ} \mathrm{C}$.
An RLIM resistance range of $6 \mathrm{k} \Omega$ to $60 \mathrm{k} \Omega$ corresponds to a current-limit threshold of 30 mV to 300 mV . Use $1 \%$ tolerance resistors when adjusting the current limit to minimize error in the current-limit threshold.

## Input Capacitor

The input filter capacitor reduces peak current drawn from the power source and reduces noise and voltage ripple on the input caused by the switching circuitry. The input capacitor must meet the ripple current requirement (IRMS) imposed by the switching currents as defined by the following equation:

$$
I_{\mathrm{RMS}}=\mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})} \frac{\sqrt{\mathrm{V}_{\mathrm{OUT}}\left(\mathrm{~V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{OUT}}\right)}}{\mathrm{V}_{\mathrm{IN}}}
$$

IRMS attains a maximum value when the input voltage equals twice the output voltage ( V IN $=2 \mathrm{VOUT}$ ), so $\operatorname{IRMS}(\operatorname{MAX})=\operatorname{ILOAD}(M A X) / 2$. For most applications, nontantalum capacitors (ceramic, aluminum, polymer, or OS-CON) are preferred at the inputs due to the robustness of nontantalum capacitors to accommodate high inrush currents of systems being powered from very low impedance sources. Additionally, two (or more) smallervalue low-ESR capacitors should be connected in parallel to reduce high-frequency noise.

## Output Capacitor

The key selection parameters for the output capacitor are capacitance value, ESR, and voltage rating. These parameters affect the overall stability, output ripple voltage, and transient response. The output ripple has two components: variations in the charge stored in the output capacitor, and the voltage drop across the capacitor's ESR caused by the current flowing into and out of the capacitor:

$$
\Delta \mathrm{V}_{\mathrm{RIPPLE}}=\Delta \mathrm{V}_{\mathrm{ESR}}+\Delta \mathrm{V}_{\mathrm{Q}}
$$

The output-voltage ripple as a consequence of the ESR and the output capacitance is:

$$
\begin{aligned}
& \Delta V_{E S R}=I_{P-P} \times E S R \\
& \Delta V_{Q}=\frac{I_{P-P}}{8 \times C_{O U T} \times f_{S W}} \\
& I_{P-P}=\left(\frac{V_{I N}-V_{O U T}}{f_{S W} \times L}\right) \times\left(\frac{V_{O U T}}{V_{I N}}\right)
\end{aligned}
$$

where IP-P is the peak-to-peak inductor current ripple (see the Inductor Selection section). Use these equations for initial capacitor selection. Decide on the final values by testing a prototype or an evaluation circuit.
Check the output capacitor against load-transient response requirements. The allowable deviation of the output voltage during fast load transients determines the capacitor output capacitance, ESR, and equivalent series inductance (ESL). The output capacitor supplies the load current during a load step until the controller responds with a higher duty cycle. The response time (tRESPONSE) depends on the closed-loop bandwidth of the converter (see the Compensation Design section). The resistive drop across the ESR of the output capacitor, the voltage drop across the ESL ( $\Delta \mathrm{V}_{\mathrm{ESL}}$ ) of the capacitor, and the capacitor discharge, cause a voltage droop during the load step.
Use a combination of low-ESR tantalum/aluminum electrolytic and ceramic capacitors for improved transient load and voltage ripple performance. Nonleaded capacitors and capacitors in parallel help reduce the ESL. Keep the maximum output-voltage deviation below the tolerable limits of the load. Use the following equations to calculate the required ESR, ESL, and capacitance value during a load step:

$$
\begin{aligned}
& \mathrm{ESR}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{I_{\text {STEP }}} \\
& \mathrm{C}_{\mathrm{OUT}}=\frac{I_{\text {STEP }} \times t_{\text {RESPONSE }}}{\Delta \mathrm{V}_{\mathrm{Q}}} \\
& \mathrm{ESL}=\frac{\Delta \mathrm{V}_{\text {ESL }} \times \mathrm{t}_{\text {STEP }}}{I_{\text {STEP }}} \\
& \mathrm{t}_{\text {RESPONSE }} \cong \frac{1}{3 \times \mathrm{f}_{\mathrm{O}}}
\end{aligned}
$$

where ISTEP is the load step, tSTEP is the rise time of the load step, tRESPONSE is the response time of the controller, and fo is the closed-loop crossover frequency.

## 40V, High-Performance, Synchronous Buck Controller

## Compensation Design

The MAX15046 provides an internal transconductance amplifier with the inverting input and the output available for external frequency compensation. The flexibility of external compensation offers wide selection of output filtering components, especially the output capacitor. Use high-ESR aluminum electrolytic capacitors for costsensitive applications. Use low-ESR tantalum or ceramic capacitors at the output for size-sensitive applications. The high switching frequency of the MAX15046 allows the use of ceramic capacitors at the output. Choose all passive power components to meet the output ripple, component size, and component cost requirements. Choose the compensation components for the error amplifier to achieve the desired closed-loop bandwidth and phase margin.
To choose the appropriate compensation network type, the power-supply poles and zeros, the zero-crossover frequency, and the type of the output capacitor must be determined first.

In a buck converter, the LC filter in the output stage introduces a pair of complex poles at the following frequency:

$$
f_{\mathrm{PO}}=\frac{1}{2 \pi \times \sqrt{\mathrm{L}_{\mathrm{OUT}} \times \mathrm{C}_{\mathrm{OUT}}}}
$$

The output capacitor introduces a zero at:

$$
\mathrm{f}_{\mathrm{ZO}}=\frac{1}{2 \pi \times E S R \times \mathrm{C}_{\text {OUT }}}
$$

where ESR is the equivalent series resistance of the output capacitor.
The loop-gain crossover frequency (fo), where the loop gain equals 1 (0dB) should be set below 1/10th of the switching frequency:

$$
\mathrm{f}_{\mathrm{O}} \leq \frac{\mathrm{f}_{\mathrm{SW}}}{10}
$$

Choosing a lower crossover frequency reduces the effects of noise pickup into the feedback loop, such as jittery duty cycle.

To maintain a stable system, two stability criteria must be met:

1) The phase shift at the crossover frequency, fo, must be less than $180^{\circ}$. In other words, the phase margin of the loop must be greater than zero.
2) The gain at the frequency where the phase shift is $-180^{\circ}$ (gain margin) must be less than 1.
Maintain a phase margin of around $60^{\circ}$ to achieve a robust loop stability and well-behaved transient response.
When using an electrolytic or large-ESR tantalum output capacitor, the capacitor ESR zero fzo typically occurs between the LC poles and the crossover frequency fo ( $\mathrm{fPO}<\mathrm{fzO}<\mathrm{fO}$ ). Choose the Type II (PI-Proportional, Integral) compensation network.
When using a ceramic or low-ESR tantalum output capacitor, the capacitor ESR zero typically occurs above the desired crossover frequency fo, that is fpo < fo < fzo. Choose the Type III (PID- Proportional, Integral, and Derivative) compensation network.

Type II Compensation Network (Figure 3)
If fzo is lower than fo and close to fPO, the phase lead of the capacitor ESR zero almost cancels the phase loss of one of the complex poles of the LC filter around the crossover frequency. Use a Type II compensation network with a midband zero and a high-frequency pole to stabilize the loop. In Figure 3, RF and CF introduce a midband zero (fZ1). RF and CCF in the Type II compensation network provide a high-frequency pole (fp1), which mitigates the effects of the output high-frequency ripple.
Use the following steps to calculate the component values for Type II compensation network as shown in Figure 3:

1) Calculate the gain of the modulator (GAINMOD), comprised of the regulator's pulse-width modulator, LC filter, feedback divider, and associated circuitry at crossover frequency:

$$
\mathrm{GAIN}_{\mathrm{MOD}}=\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{RAMP}}} \times \frac{\mathrm{ESR}}{\left(2 \pi \times \mathrm{f}_{\mathrm{O}} \times \mathrm{L}_{\mathrm{OUT}}\right)} \times \frac{\mathrm{V}_{\mathrm{FB}}}{\mathrm{~V}_{\mathrm{OUT}}}
$$

where VIN is the input voltage of the regulator, VRAMP is the amplitude of the ramp in the pulse-width modulator, $\mathrm{V}_{\mathrm{FB}}$ is the FB input voltage set point ( 0.6 V typically, see the Electrical Characteristics table), and Vout is the desired output voltage.
The gain of the error amplifier (GAINEA) in midband frequencies is:

$$
\text { GAINEA }=\mathrm{gM} \times \mathrm{RF}_{\mathrm{F}}
$$

where gm is the transconductance of the error amplifier.

## 40V, High-Performance, Synchronous Buck Controller

The total loop gain, which is the product of the modulator gain and the error-amplifier gain at fo, is:

1) GAIN $_{\text {MOD }} \times$ GAIN $_{E A}=1$

So:

$$
\frac{V_{I N}}{V_{\text {OSC }}} \times \frac{E S R}{\left(2 \pi \times f_{O} \times L_{\text {OUT }}\right)} \times \frac{V_{\text {FB }}}{V_{\text {OUT }}} \times g_{M} \times R_{F}=1
$$

Solving for $R_{F}$ :

$$
R_{F}=\frac{V_{O S C} \times\left(2 \pi \times f_{\mathrm{O}} \times L_{\text {OUT }}\right) \times V_{\text {OUT }}}{V_{F B} \times V_{I N} \times g_{M} \times E S R}
$$

2) Set a midband zero ( $\mathrm{fz1}$ ) at $0.75 \times \mathrm{fPO}$ (to cancel one of the LC poles):

$$
f_{Z 1}=\frac{1}{2 \pi \times R_{F} \times C_{F}}=0.75 \times f_{P O}
$$

Solving for CF:

$$
C_{F}=\frac{1}{2 \pi \times R_{F} \times f_{P O} \times 0.75}
$$

3) Place a high-frequency pole at $\mathrm{fP} 1=0.5 \times \mathrm{fSW}$ (to attenuate the ripple at the switching frequency fsw) and calculate CCF using the following equation:

$$
\mathrm{C}_{\mathrm{CF}}=\frac{1}{\pi \times \mathrm{R}_{F} \times \mathrm{f}_{\mathrm{SW}}-\frac{1}{\mathrm{C}_{F}}}
$$

Figure 3. Type II Compensation Network

Type III Compensation Network (See Figure 4)
When using a low-ESR tantalum or ceramic type, the ESR-induced zero frequency is usually above the targeted zero crossover frequency (fO). Use Type III compensation. Type III compensation provides two zeros and three poles at the following frequencies:

$$
\begin{aligned}
& \mathrm{f}_{\mathrm{Z} 1}=\frac{1}{2 \pi \times \mathrm{R}_{\mathrm{F}} \times \mathrm{C}_{\mathrm{F}}} \\
& \mathrm{f}_{\mathrm{Z} 2}=\frac{1}{2 \pi \times \mathrm{C}_{\mathrm{I}} \times\left(\mathrm{R}_{1}+\mathrm{R}_{\boldsymbol{l}}\right)}
\end{aligned}
$$

Two midband zeros (fz1 and fz2) cancel the pair of complex poles introduced by the LC filter:

$$
f \mathrm{fP}_{1}=0
$$

fP1 introduces a pole at zero frequency (integrator) for nulling DC output-voltage errors:

$$
f_{P 2}=\frac{1}{2 \pi \times R_{\mid} \times C_{\mid}}
$$

Depending on the location of the ESR zero (fzo), use fp2 to cancel fzo, or to provide additional attenuation of the high-frequency output ripple:

$$
f_{P 3}=\frac{1}{2 \pi \times R_{F} \times \frac{C_{F} \times C_{C F}}{C_{F}+C_{C F}}}
$$

fP3 attenuates the high-frequency output ripple.
Place the zeros and poles such that the phase margin peaks around fo.
Ensure that RF >> 2/gm and the parallel resistance of $R_{1}, R_{2}$, and $R_{l}$ is greater than $1 / \mathrm{gm}$. Otherwise, a $180^{\circ}$ phase shift is introduced to the response making the loop unstable.
Use the following compensation procedures:

1) With RF >> $10 \mathrm{k} \Omega$, place the first zero ( $\mathrm{f} \mathrm{Z}_{1}$ ) at 0.8 x fPO:

$$
\mathrm{f}_{\mathrm{Z} 1}=\frac{1}{2 \pi \times \mathrm{R}_{\mathrm{F}} \times \mathrm{C}_{\mathrm{F}}}=0.8 \times \mathrm{f}_{\mathrm{PO}}
$$

## 40V, High-Performance, Synchronous Buck Controller

So:

$$
C_{F}=\frac{1}{2 \pi \times R_{F} \times 0.8 \times f_{P O}}
$$

2) The gain of the modulator (GAINMOD), comprised of the pulse-width modulator, LC filter, feedback divider, and associated circuitry at crossover frequency is:

$$
\text { GAIN }_{\text {MOD }}=\frac{V_{I N}}{V_{\text {RAMP }}} \times \frac{1}{\left(2 \pi \times f_{O}\right)^{2} \times L_{\text {OUT }} \times \mathrm{C}_{\mathrm{OUT}}}
$$

The gain of the error amplifier (GAINEA) in midband frequencies is:

$$
\operatorname{GAIN}_{E A}=2 \pi \times f_{O} \times C_{\mid} \times R_{F}
$$

The total loop gain as the product of the modulator gain and the error amplifier gain at fo is 1 .

$$
\mathrm{GAIN}_{\mathrm{MOD}} \times \mathrm{GAIN}_{\mathrm{EA}}=1
$$

So:

$$
\frac{V_{\text {IN }}}{V_{\text {RAMP }}} \times \frac{1}{\left(2 \pi \times f_{O}\right)^{2} \times C_{\text {OUT }} \times L_{\text {OUT }}} \times 2 \pi \times f_{O} \times C_{I} \times R_{F}=1
$$

Solving for $\mathrm{C}_{\mathrm{I}}$ :

$$
C_{I}=\frac{V_{\text {RAMP }} \times\left(2 \pi \times f_{\mathrm{O}} \times \mathrm{L}_{\mathrm{OUT}} \times \mathrm{C}_{\mathrm{OUT}}\right)}{\mathrm{V}_{\mathrm{IN}} \times R_{\mathrm{F}}}
$$

3) Use the second pole (fP2) to cancel fZo when fPO < fo $<\mathrm{fZO}<\mathrm{fSW} / 2$. The frequency response of the loop gain does not flatten out soon after the OdB crossover, and maintains $-20 \mathrm{~dB} /$ decade slope up to $1 / 2$ of the switching frequency. This is likely to occur if the output capacitor is low-ESR tantalum. Set fp2 $=\mathrm{fzO}$.
When using a ceramic capacitor, the capacitor ESR zero (fzo) is likely to be located even above one half of the switching frequency, fPO < fO < fSW/2 < fZO. In this case, place the frequency of the second pole (fp2) high enough in order not to significantly erode the phase margin at the crossover frequency. For example, set fp2 at 5 x fo so that the contribution to phase loss at the crossover frequency fo is only about $11^{\circ}$ :

$$
\mathrm{fP} 2=5 \times \mathrm{fO}
$$

Once fP2 is known, calculate RI:

$$
R_{I}=\frac{1}{2 \pi \times f_{P 2} \times C_{\mid}}
$$

4) Place the second zero (fz2) at $0.2 \times$ fo or at fpo, whichever is lower and calculate $\mathrm{R}_{1}$ using the following equation:

$$
\mathrm{R}_{1}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{Z} 2} \times \mathrm{C}_{\mid}}-\mathrm{R}_{\mathrm{l}}
$$

5) Place the third pole (fP3) at one half the switching frequency and calculate CCF:

$$
C_{C F}=\frac{C_{F}}{\left(2 \pi \times 0.5 \times f_{S W} \times R_{F} \times C_{F}\right)-1}
$$

6) Calculate R2 as:

$$
R_{2}=\frac{V_{F B}}{V_{\mathrm{OUT}}-V_{\mathrm{FB}}} \times R_{1}
$$

MOSFET Selection
The MAX15046 step-down controller drives two external logic-level n-channel MOSFETs. The key selection parameters to choose these MOSFETs include:

- On-resistance (RDS(ON))
- Maximum Drain-to-Source Voltage (VDS(MAX))
- Minimum Threshold Voltage (VTH(MIN)
- Total Gate Charge (QG)
- Reverse Transfer Capacitance (CRSS)
- Power Dissipation

The two n-channel MOSFETs must be a logic-level type with guaranteed on-resistance specifications at $\mathrm{VGS}=4.5 \mathrm{~V}$. For maximum efficiency, choose a highside MOSFET that has conduction losses equal to the switching losses at the typical input voltage. Ensure that the conduction losses at minimum input voltage do not exceed the MOSFET package thermal limits, or violate the overall thermal budget. Also ensure that the conduction losses plus switching losses at the maximum input voltage do not exceed package ratings or violate the

## 40V, High-Performance, Synchronous Buck Controller

Figure 4. Type III Compensation Network
overall thermal budget. Ensure that the DL gate driver can drive the low-side MOSFET. In particular, check that the $\mathrm{dv} / \mathrm{dt}$ caused by the high-side MOSFET turning on does not pull up the low-side MOSFET gate through the drain-to-gate capacitance of the low-side MOSFET, which is the most frequent cause of crossconduction problems.
Check power dissipation when using the internal linear regulator to power the gate drivers. Select MOSFETs with low gate charge so that VCC can power both drivers without overheating the device:

$$
\text { PDRIVE }=\text { VCC } \times \text { QG_TOTAL } \times \text { fSW }
$$

where $Q_{G}$ TOTAL is the sum of the gate charges of the two external MOSFETs.

## Boost Capacitor and Diode Selection

The MAX15046 uses a bootstrap circuit to generate the necessary gate-to-source voltage to turn on the high-side MOSFET. The selected n-channel high-side MOSFET determines the appropriate boost capacitance value (CBST in the Typical Application Circuits) according to the following equation:

$$
\mathrm{C}_{\mathrm{BST}}=\frac{\mathrm{QG}}{\Delta \mathrm{~V}_{\mathrm{BST}}}
$$

where $Q_{G}$ is the total gate charge of the high-side MOSFET and $\triangle V_{B S T}$ is the voltage variation allowed on the high-side MOSFET driver after turn-on. Choose $\Delta V_{\text {BST }}$ such that the available gate-drive voltage is not significantly degraded (e.g. $\Delta \mathrm{V}$ BST $=100 \mathrm{mV}$ to 300 mV ) when determining CBST.

Use a low-ESR ceramic capacitor as the boost capacitor with a minimum value of 100 nF .

A small-signal diode can be used for the bootstrap circuit and must have a minimum voltage rating of VIN + 3 V to withstand the maximum BST voltage. The average forward current of the diode should meet the following requirement:

$$
\text { IF > QGATE } \times \text { fSW }
$$

where QGATE is the gate charges of the low-side MOSFET.
Power Dissipation
The maximum power dissipation of the device depends on the thermal resistance from the die to the ambient environment and the ambient temperature. The thermal resistance depends on the device package, PCB copper area, other thermal mass, and airflow.

The power dissipated into the package (PT) depends on the supply configuration (see the Typical Application Circuits). Use the following equation to calculate power dissipation:

$$
\text { PT }=\text { VIN } \times\left[Q_{G} \text { TOTAL } \times f S W+I_{Q}\right]
$$

where $I_{Q}$ is the quiescent supply current at the switching frequency. See the IIN vs. Switching Frequency graph in the Typical Operating Characteristics for the IQ.
Use the following equation to estimate the temperature rise of the die:

$$
T J=T_{A}+\left(P_{T} \times \theta J A\right)
$$

where $\theta \mathrm{JA}$ is the junction-to-ambient thermal impedance of the package, $\mathrm{P}_{\mathrm{T}}$ is power dissipated in the device, and $T_{A}$ is the ambient temperature. The $\theta_{J A}$ is $103.7^{\circ} \mathrm{C} / \mathrm{W}$ for the 16 -pin QSOP and $53^{\circ} \mathrm{C} / \mathrm{W}$ for the 16-pin QSOPEP package on multilayer boards, with the conditions specified by the respective JEDEC standards (JESD51-5, JESD51-7). An accurate estimation of the junction temperature requires a direct measurement of the case temperature (TC) when actual operating conditions significantly deviate from those described in the JEDEC standards. The junction temperature is then:

$$
T J=T C+(P T \times \theta J C)
$$

Use $37^{\circ} \mathrm{C} / \mathrm{W}$ as $\theta \mathrm{JC}$ thermal impedance for the 16 -pin QSOP package and $6^{\circ} \mathrm{C} / \mathrm{W}$ for the 16-pin QSOP-EP package. The case-to-ambient thermal impedance ( $\theta$ CA) is dependent on how well the heat is transferred from the PCB to the ambient. Use large copper areas to keep the PCB temperature low.

## 40V, High-Performance, Synchronous Buck Controller

## PCB Layout Guidelines

Careful PCB layout is critical to achieve clean and stable operation. The switching power stage requires particular attention. Follow these guidelines for good PCB layout:

1) Place decoupling capacitors as close as possible to the IC. Connect the power ground plane (connected to PGND) and signal ground plane (connected to GND) at one point near the device.
2) Connect input and output capacitors to the power ground plane; connect all other capacitors to the signal ground plane.
3) Keep the high-current paths as short and wide as possible. Keep the path of switching current (C2 to IN and C2 to PGND) short. Avoid vias in the switching paths.
4) Connect CSP to the drain of the low-side FET using a Kelvin connection for accurate current-limit sensing.
5) Ensure all feedback connections are short and direct. Place the feedback resistors as close as possible to the IC.
6) Route high-speed switching nodes (BST, LX, DH, and DL ) away from sensitive analog areas (RT, FB, COMP, and LIM).

## 24V Supply, 3.3V Output Operation

Typical Application Circuit 1 in the Typical Application Circuits section shows an application circuit that operates out of 24 V and outputs up to 10 A at 3.3 V . R5 sets the switching frequency to 350 kHz .

Single 4.5V to 5.5V Supply Operation
Typical Application Circuit 2 in the Typical Application Circuits section shows an application circuit for a single +4.5 V to +5.5 V power-supply operation.

## Auxiliary 5V Supply Operation
