

High-Voltage, Step-Down Controller in TSOT6

FEATURES

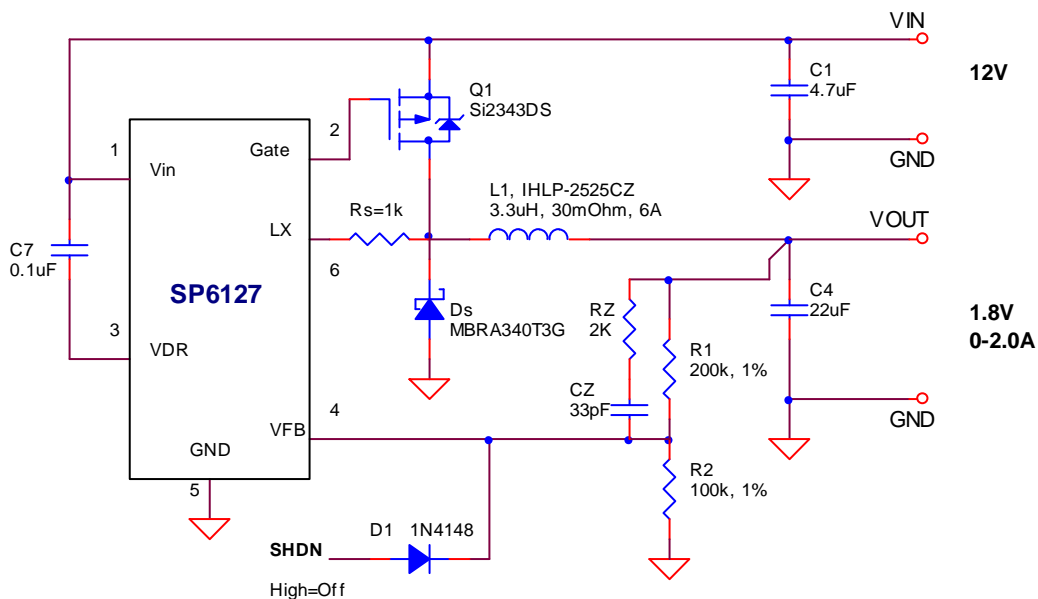

- Wide 4.5V – 29V Input Voltage Range
- Internal compensation
- Built-in High-Current PMOS Driver
- Adjustable Overcurrent Protection
- Internal soft start
- 900kHz Constant Frequency Operation
- 0.6V Reference Voltage
- 1% output setpoint accuracy
- Lead Free, RoHS Compliant Package:
Small 6-pin TSOT

DESCRIPTION

The SP6127 is a PWM controlled step down (buck) voltage mode regulator with V_{IN} feedforward and internal Type-II compensation. It operates from 4.5V to 29V V_{IN} , making it suitable for 5V, 12V and 24V applications. By using a PMOS driver, this device is capable of operating at 100% duty cycle. The high-side driver is designed to drive the gate 5V below V_{IN} . The programmable overcurrent protection is based on the high-side MOSFET's ON resistance sensing and allows setting the overcurrent protection value up to 300mV threshold (measured between V_{IN} -LX). The SP6127 is available in a space-saving 6-pin TSOT package making it the smallest controller available capable of operating from 24VDC supplies.

TYPICAL APPLICATION CIRCUIT

ABSOLUTE MAXIMUM RATINGS

These are stress ratings only, and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

| | |
|---|----------------------------------|
| Input Voltage..... | -0.3V to 30V |
| Lx..... | -2V to 30V |
| FB..... | -0.3V to 5.5V |
| Storage Temperature..... | -65 °C to 150 °C |
| Junction Temperature..... | -40°C to 125°C |
| Lead Temperature (Soldering, 10 sec)..... | 300 °C |
| ESD Rating..... | 1kV LX, 2kV all other nodes, HBM |

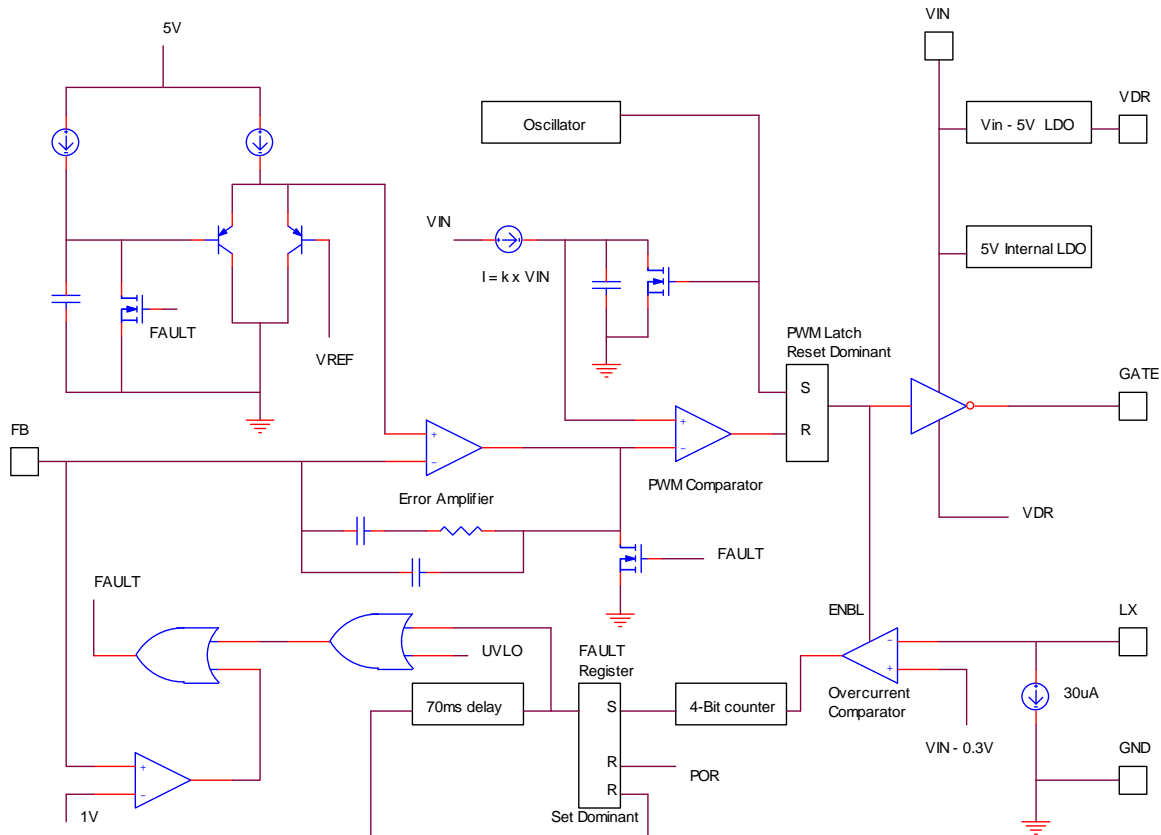

ELECTRICAL SPECIFICATIONS

Specifications are for $T_{AMB}=T_J=25^{\circ}C$, and those denoted by \blacklozenge apply over the full operating range, $-40^{\circ}C < T_J < 125^{\circ}C$. Unless otherwise specified: $V_{IN} = 4.5V$ to $29V$, $C_{IN} = 4.7\mu F$.

| PARAMETER | MIN | TYP | MAX | UNITS | \blacklozenge | CONDITIONS |

| PIN # | PIN NAME | DESCRIPTION |
|-------|----------|---|
| 1 | VIN | Input power supply for the controller. Place input decoupling capacitor as close as possible to this pin. |
| 2 | GATE | Connect to the gate terminal of the external P-channel MOSFET. |
| 3 | VDR | Power supply for the internal driver. This voltage is internally regulated to about 5V below VIN. Place a 0.1µF decoupling capacitor between VDR and VIN as close as possible to the IC. |
| 4 | FB | Regulator feedback input. Connect to a resistive voltage-divider network to set the output voltage. This pin can be also used for ON/OFF control. If this pin is pulled above 1V the P-channel driver is disabled and controller resets internal soft start circuit. |
| 5 | GND | Ground pin. |
| 6 | LX | This pin is used as a current limit input for the internal current limit comparator. Connect to the drain pin of the external MOSFET through an optional resistor. Internal threshold is pre-set to 300mV nominal and can be decreased by changing the external resistor based on the following formula: $V_{TRSHLD} = 300mV - 30\mu A * R$ |

BLOCK DIAGRAM

The SP6127 is a fixed frequency, Voltage-mode, non-synchronous PWM controller optimized for minimum component, small form factor and cost effectiveness. It has been designed for single-supply operation ranging from 4.5V to 29V. SP6127 has Type-II internal compensation for use with Electrolytic/Tantalum output capacitors. For ceramic capacitors Type-III compensation can be implemented by simply adding an R and C between output and Feedback. A precision 0.6V reference, present on the positive terminal of the Error Amplifier, permits programming of the output voltage down to 0.6V via the FB pin. The output of the Error Amplifier is internally compared to a feed-forward ($V_{IN}/5$ peak-to-peak) ramp and generates the PWM control. Timing is governed by an internal oscillator that sets the PWM frequency at 900kHz.

SP6127 contains useful protection features. Overcurrent protection is based on the high-side MOSFET's $R_{DS(ON)}$ and is programmable via a resistor placed at LX node. Under-Voltage Lock-Out (UVLO) ensures that the controller starts functioning only when sufficient voltage exists for powering IC's internal circuitry.

SP6127 Loop Compensation

The SP6127 includes Type-II internal compensation components for loop compensation. External compensation components are not required for systems with tantalum or aluminum electrolytic output capacitors with sufficiently high ESR. Use the condition below as a guideline to determine whether or not the internal compensation is sufficient for your design.

Type-II internal compensation is sufficient if the following condition is met:

$$f_{ESRZERO} < f_{DBPOLE} \dots\dots\dots (1)$$

where:

$$f_{ESRZERO} = \frac{1}{2\pi \cdot R_{ESR} \cdot C_{OUT}} \dots\dots\dots (2)$$

$$f_{DBPOLE} = \frac{1}{2\pi \cdot \sqrt{L} \cdot C_{OUT}} \dots\dots\dots (3)$$

Creating a Type-III compensation Network

The above condition requires the ESR zero to be at a lower frequency than the double-pole from the LC filter. If this condition is not met, Type-III compensation should be used and can be accomplished by placing a series RC combination in parallel with R1 as shown below. The value of CZ can be calculated as follows and RZ selected from table 1.

$$CZ = \frac{\sqrt{L \cdot C}}{1.25 \times R1} \dots\dots\dots (4)$$

| $f_{ESRZERO} / f_{DBPOLE}$ | Rz |
|----------------------------|------|
| 1X | 50KΩ |
| 2X | 40KΩ |
| 3X | 30KΩ |
| 5X | 10KΩ |
| >= 10X | 2KΩ |

Table1- Selection of Rz

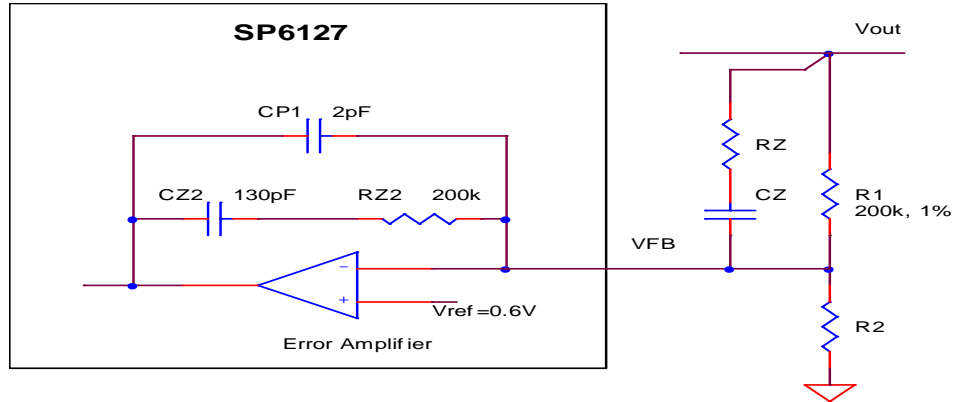

Figure 1- RZ and CZ in conjunction with internal compensation components form a Type-III compensation network

Loop Compensation Example 1- A converter utilizing a SP6127 has a 3.3μH inductor and a 22μF/5mΩ ceramic capacitor. Determine whether Type-III compensation is needed.

From equation (2) $f_{ESRZERO} = 1.45\text{MHz}$. From equation (3) $f_{DBPOLE} = 18.4\text{ kHz}$. Since the condition specified in (1) is not met, Type-III compensation must be used by adding external components RZ and CZ. Using equation (4) CZ is calculated to be 34pF (use 33pF). Following the guideline given in table 1, a 2kΩ RZ should be used.

The steps followed in example 1 were used to compensate the typical application circuit shown on page 1. Satisfactory frequency

response of the circuit, seen in figure 2, validates the above procedure.

Loop Compensation Example 2- A converter utilizing the SP6127 has a 3.3μH inductor and a 220μF, 82mΩ Aluminum Electrolytic capacitor. Determine whether Type-III compensation is needed.

From equation (2) $f_{ESRZERO} = 8.8\text{kHz}$. From equation (3) $f_{DBPOLE} = 5.9\text{kHz}$. Since the condition specified in (1) is not met, Type-III compensation needs to be used by adding external components RZ and CZ. Using equation (4) CZ is calculated 108pF (use 100 pF). Since $f_{ESRZERO} / f_{DBPOLE}$ is approximately 2, RZ must be set at 40kΩ.

Figure 2- Satisfactory frequency response of typical application circuit shown on page 1. Crossover frequency f_c is 100kHz with a corresponding phase margin of 60 degrees.

Overcurrent Protection (OCP)

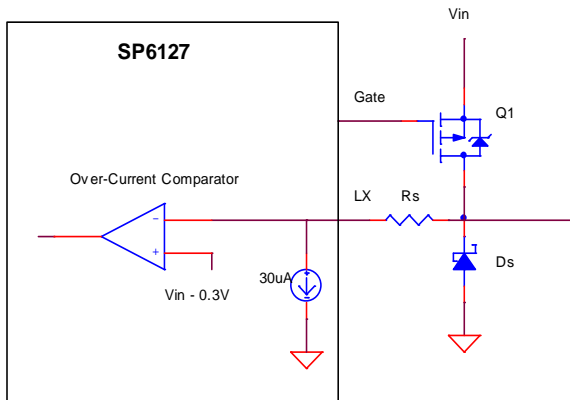

Figure 3 Overcurrent protection circuit

The overcurrent protection (OCP) circuit functions by monitoring the voltage across the high-side FET Q1. When this voltage exceeds 0.3V, the overcurrent comparator triggers and the controller enters hiccup mode. For example if Q1 has $R_{DS(ON)}=0.1\Omega$, then the overcurrent will trigger at $I = 0.3V/0.1\Omega=3A$. To program a lower overcurrent use a resistor R_s as shown in figure 1. Calculate R_s from:

$$R_s = \frac{0.3 - (1.15 \times I_{out} \times R_{ds(on)} \times K_t)}{30\mu A} \dots(5)$$

Where:

1.15 is used to calculate peak inductor current which is nominally 15% higher than average output current

$R_{DS(ON)}$ is MOSFET ON-resistance rating

K_t is a multiplier that accounts for increase in $R_{DS(ON)}$ due to temperature

Example: A switching MOSFET used with SP6127 has $R_{DS(ON)}$ of 0.08Ω and K_t is 1.5. Program the over-current circuit so that maximum output is 2A.

$$R_s = \frac{0.3 - (1.15 \times 2A \times 0.08\Omega \times 1.5)}{30\mu A}$$

$R_s=800\Omega$

Using the above equation there is good agreement between calculated and test results

for R_s in the range of $0.5k\Omega$ to $3k\Omega$. For R_s larger than $3k\Omega$, test results are lower than those predicted by (5), due to circuit parasitics. Therefore the maximum value of R_s should be limited to $3k\Omega$.

Note that in order to safeguard against false overcurrent trigger due to transients, there is a 150ns delay between the turn on of the MOSFET and when OCP circuit is activated. As a consequence at very high V_o/V_{IN} ratio, where MOSFET on-time is less than 150ns, the OCP circuit will not detect overcurrent.

Using the ON/OFF Function

The Feedback pin serves a dual role of ON/OFF control. The MOSFET driver is disabled when a voltage greater than 1V is applied at the FB pin. Maximum voltage rating of this pin is 5.5V. The controlling signal should be applied through a small signal diode as shown on page 1.

Please note that an optional 10kΩ bleeding resistor across the output helps keep the output capacitor discharged under no load condition.

Programming the Output Voltage

To program the output voltage, calculate R_2 using the following equation:

$$R_2 = \frac{R_1}{\left(\frac{V_{out}}{V_{ref}} - 1\right)}$$

Where:

$V_{REF}=0.6$ is the reference voltage of the SP6127
 $R_1=200k\Omega$ is a fixed-value resistor that, in addition to being a voltage divider, it is part of the compensation network. In order to simplify compensation calculations, R_1 is fixed at $200k\Omega$.

Soft Start

Soft Start is preset internally to 5ms (nominal). Internal Soft Start eliminates the need for the external capacitor CSS that is commonly used to program this function.

MOSFET Gate Drive

The P-channel drive is derived through an internal regulator that generates VIN-5V. This pin (VDR) must be connected to VIN with a 0.1µF decoupling capacitor. The gate drive circuit swings between VIN and VIN-5 and employs powerful drivers for efficient switching of the P-channel MOSFET.

Power MOSFET Selection

Select the Power MOSFET for Voltage rating BVDSS, On resistance RDS(ON), and thermal resistance RTHJA. BVDSS should be about twice as high as VIN in order to guard against switching transients. The recommended MOSFET voltage rating for VIN of 5V, 12V and 24V is 12V, 30V and 40V respectively. RDS(ON) must be selected such that when operating at peak current and junction temperature, the Overcurrent threshold of the SP6127 is not exceeded. Allowing 50% for temperature coefficient of RDS(ON) and 15% for inductor current ripple, the following expression can be used:

$$RDS(ON) \leq \left(\frac{0.3V}{1.5 \times 1.15 \times I_{out}} \right)$$

Within this constraint, selecting MOSFETs with lower RDS(ON) will reduce conduction losses at the expense of increased switching losses. As a rule of thumb, select the highest RDS(ON) MOSFET that meets the above criteria. Switching losses can be assumed to roughly equal to the conduction losses. A simplified expression for conduction losses is given by:

$$P_{cond} = I_{out}^2 \times RDS(ON) \times \left(\frac{V_{out}}{V_{in}} \right)$$

The MOSFET's junction temperature can be estimated from:

$$T = (2 \times P_c \times R_{thja}) + T_{ambient}$$

Schottky Rectifier selection

Select the Schottky Diode for Voltage rating VR, Forward voltage Vf, and thermal resistance RTHJA. The Voltage rating should be selected using the same guidelines outlined for MOSFET

voltage selection. For a low duty cycle application such as the circuit shown on first page, the Schottky diode is conducting most of the time and its conduction losses are the largest component of losses in the converter. Conduction losses can be estimated from:

$$P_c = V_f \times I_{out} \times \left(1 - \frac{V_{out}}{V_{in}} \right)$$

where:

Vf is diode forward voltage at IOUT

The Schottky diode's AC losses due to its switching capacitance are negligible.

Inductor Selection

Select the Inductor for inductance L and saturation current ISAT. Select an inductor with ISAT higher than the programmed overcurrent. Calculate inductance from:

$$L = (V_{in} - V_{out}) \times \left(\frac{V_{out}}{V_{in}} \right) \times \left(\frac{1}{f} \right) \times \left(\frac{1}{I_{rip}} \right)$$

where:

VIN is converter input voltage

VOUT is converter output voltage

f is switching frequency

IRIP is inductor peak-to-peak current ripple (nominally set to 30% of IOUT)

Keep in mind that a higher IRIP results in a smaller inductor which has the advantages of small size, low DC equivalent resistance DCR, high saturation current ISAT and allows the use of a lower output capacitance to meet a given step load transient. A higher IRIP, however, increases the output voltage ripple and increases the current at which converter enters Discontinuous Conduction Mode. The output current at which converter enters DCM is ½ of IRIP. Note that a negative current step load that drives the converter into DCM will result in a large output voltage transient. Therefore the lowest current for a step load should be larger than ½ of IRIP.

Output Capacitor Selection

Select the output capacitor for voltage rating, capacitance and Equivalent Series Resistance (ESR). Nominally the voltage rating is selected to be twice as large as the output voltage. Select the capacitance to satisfy the specification for output voltage overshoot/undershoot caused by current step load. A steady-state output current I_{OUT} corresponds to inductor stored energy of $\frac{1}{2} L I_{OUT}^2$. A sudden decrease in I_{OUT} forces the energy surplus in L to be absorbed by C_{OUT} . This causes an overshoot in output voltage that is corrected by the reduced duty cycle of the power switch. Use the following equation to calculate C_{OUT} :

$$C_{out} = L \times \left(\frac{I_2^2 - I_1^2}{V_{os}^2 - V_{out}^2} \right)$$

Where:

L is the output inductance

I_2 is the step load high current

I_1 is the step load low current

V_{os} is output voltage including overshoot

V_{OUT} is steady state output voltage

Output voltage undershoot calculation is more complicated. Test results for SP6127 buck circuits show that undershoot is approximately equal to overshoot. Therefore the above equation provides a satisfactory method for calculating C_{OUT} .

Select ESR such that output voltage ripple (V_{RIP}) specification is met. There are two components to V_{RIP} : The first component arises from charge transferred to and from C_{OUT} during each cycle. The second component of V_{RIP} is due to inductor ripple current flowing through the output capacitor's ESR. It can be calculated from:

$$V_{rip} = I_{rip} \times \sqrt{ESR^2 + \left(\frac{1}{8 \times C_{out} \times fs} \right)^2}$$

Where:

I_{RIP} is inductor ripple current

fs is switching frequency

C_{OUT} is output capacitor calculated above

Note that a smaller inductor results in a higher I_{RIP} , therefore requiring a larger C_{OUT} and/or lower ESR in order to meet V_{RIP} .

Input Capacitor Selection

Select the input capacitor for Voltage, Capacitance, ripple current, ESR and ESL. Voltage rating is nominally selected to be twice the input voltage. The RMS value of the input capacitor current, assuming a low inductor ripple current (I_{RIP}), can be calculated from:

$$I_{cin} = I_{out} \times \sqrt{D(1-D)}$$

In general, total input voltage ripple should be kept below 1.5% of V_{IN} (not to exceed 180mV). Input voltage ripple has three components: ESR and ESL cause a step voltage drop upon turn on of the MOSFET. During on time, the capacitor discharges linearly as it supplies $I_{OUT}-I_{IN}$. The contribution to Input voltage ripple by each term can be calculated from:

$$\Delta V, C_{in} = \frac{I_{out} \times V_{out} \times (V_{in} - V_{out})}{fs \times C_{in} \times V_{in}^2}$$

$$\Delta V, ESR = ESR(I_{out} - 0.5I_{rip})$$

$$\Delta V, ESL = ESL \frac{(I_{out} - 0.5I_{rip})}{T_{rise}}$$

Where T_{RISE} is the rise time of current through capacitor

Total input voltage ripple is sum of the above:

$$\Delta V, Tot = \Delta V, C_{in} + \Delta V, ESR + \Delta V, ESL$$

In circuits where converter input voltage is applied via a mechanical switch, excessive ringing may be present at turn-on that may interfere with smooth startup of the SP6127. The addition of an inexpensive 100 μ F Aluminum Electrolytic capacitor at the input will help reduce ringing and restore a smooth startup.
