## AMIS-30532

## Micro-Stepping Motor Driver

## Introduction

The AMIS-30532 is a micro-stepping stepper motor driver for bipolar stepper motors. The chip is connected through I/O pins and an SPI interface with an external microcontroller. It has an on-chip voltage regulator, reset-output and watchdog reset, able to supply peripheral devices. The AMIS-30532 contains a current-translation table and takes the next micro-step depending on the clock signal on the "NXT" input pin and the status of the "DIR" (=direction) register or input pin. The chip provides a so-called "speed and load angle" output. This allows the creation of stall detection algorithms and control loops based on load-angle to adjust torque and speed. It is using a proprietary PWM algorithm for reliable current control.

The AMIS-30532 is implemented in I2T100 technology, enabling both high-voltage analog circuitry and digital functionality on the same chip. The chip is fully compatible with the automotive voltage requirements.

The AMIS-30532 is ideally suited for general-purpose stepper motor applications in the automotive, industrial, medical, and marine environment. With the on-chip voltage regulator it further reduces the BOM for mechatronic stepper applications.

## Key Features

- Dual H-Bridge for 2-Phase Stepper Motors
- Programmable Peak-Current up to 1.6 A Continuous ${ }^{\dagger}$ (3.0 A Short Time) using a 5-bit Current DAC
- On-Chip Current Translator
- SPI Interface
- Speed and Load Angle Output
- Seven Step Modes from Full-Step Up to 32 Micro-Steps
- Fully Integrated Current-Sense
- PWM Current Control with Automatic Selection of Fast and Slow Decay
- Low EMC PWM with Selectable Voltage Slopes
- Active Fly-Back Diodes
- Full Output Protection and Diagnosis
- Thermal Warning and Shutdown
- Compatible with 5 V and 3.3 V Microcontrollers
- Integrated 5 V Regulator to Supply External Microcontroller
- Integrated Reset Function to Reset External Microcontroller
- Integrated Watchdog Function
- These Devices are $\mathrm{Pb}-$ Free and are RoHS Compliant*

## EQUIVALENT SCHEMATICS

Following figure gives the equivalent schematics of the user relevant inputs and outputs. The diagrams are simplified representations of the circuits used.

Figure 3. In- and Output Equivalent Diagram

## PACKAGE THERMAL CHARACTERISTICS

The AMIS-30532 is available in a NQFP32 package. For cooling optimizations, the NQFP has an exposed thermal pad which has to be soldered to the PCB ground plane. The ground plane needs thermal vias to conduct the heat to the bottom layer. Figure 3 gives an example for good power distribution solutions.

For precise thermal cooling calculations the major thermal resistances of the device are given. The thermal media to which the power of the devices has to be given are:

- Static environmental air (via the case)
- PCB board copper area (via the exposed pad)

The thermal resistances are presented in Table 5: DC Parameters.

The major thermal resistances of the device are the Rth from the junction to the ambient (Rthja) and the overall Rth from the junction to exposed pad (Rthjp). In Table 5 below one can find the values for the Rthja and Rthjp, simulated according to JESD-51:

The Rthja for 2 S 2 P is simulated conform JEDEC JESD-51 as follows:

- A 4-layer printed circuit board with inner power planes and outer (top and bottom) signal layers is used
- Board thickness is 1.46 mm (FR4 PCB material)
- The 2 signal layers: $70 \mu \mathrm{~m}$ thick copper with an area of $5500 \mathrm{~mm}^{2}$ copper and $20 \%$ conductivity
- The 2 power internal planes: $36 \mu \mathrm{~m}$ thick copper with an area of $5500 \mathrm{~mm}^{2}$ copper and $90 \%$ conductivity The Rthja for 1S0P is simulated conform to JEDEC JESD-51 as follows:
- A 1-layer printed circuit board with only 1 layer
- Board thickness is 1.46 mm (FR4 PCB material)
- The layer has a thickness of $70 \mu \mathrm{~m}$ copper with an area of $5500 \mathrm{~mm}^{2}$ copper and $20 \%$ conductivity

## ELECTRICAL SPECIFICATION

## Recommend Operation Conditions

Operating ranges define the limits for functional operation and parametric characteristics of the device. Note that the functionality of the chip outside these operating
ranges is not guaranteed. Operating outside the recommended operating ranges for extended periods of time may affect device reliability.

Table 4. OPERATING RANGES

| Symbol | Parameter | Min | Max | Unit |
| :---: | :--- | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{BB}}$ | Analog DC Supply | +6 | +30 | V |
| $\mathrm{~T}_{J}$ | Junction Temperature (Note 5) | -40 | +172 | ${ }^{\circ} \mathrm{C}$ |

5. No more than 100 cumulative hours in life time above $T_{\text {tw }}$.

Table 5. DC PARAMETERS (The DC parameters are given for $V_{B B}$ and temperature in their operating ranges unless otherwise specified) Convention: currents flowing in the circuit are defined as positive.

| Symbol | Pin(s) | Parameter | Remark/Test Conditions | Min | Typ | Max | Unit |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

SUPPLY AND VOLTAGE REGULATORS

| $V_{B B}$ | $V_{B B}$ | Nominal operating supply range |  | 6 |  | 30 | V |

## FUNCTIONAL DESCRIPTION

## H-Bridge Drivers

A full H -bridge is integrated for each of the two stator windings. Each H-bridge consists of two low-side and two high-side N-type MOSFET switches. Writing logic ' 0 ' in bit <MOTEN> disables all drivers (high-impedance). Writing logic ' 1 ' in this bit enables both bridges and current can flow in the motor stator windings.

In order to avoid large currents through the H -bridge switches, it is guaranteed that the top- and bottom-switches of the same half-bridge are never conductive simultaneously (interlock delay).

A two-stage protection against shorts on motor lines is implemented. In a first stage, the current in the driver is limited. Secondly, when excessive voltage is sensed across the transistor, the transistor is switched-off.

In order to reduce the radiated/conducted emission, voltage slope control is implemented in the output switches. The output slope is defined by the gate-drain capacitance of output transistor and the (limited) current that drives the gate. There are two trimming bits for slope control (see SPI Control Parameter Overview EMC[1:0]).

The power transistors are equipped with so-called "active diodes": when a current is forced trough the transistor switch in the reverse direction, i.e. from source to drain, then the transistor is switched on. This ensures that most of the current flows through the channel of the transistor instead of through the inherent parasitic drain-bulk diode of the transistor.

Depending on the desired current range and the micro-step position at hand, the $\mathrm{R}_{\mathrm{DS}(\text { on })}$ of the low-side
transistors will be adapted such that excellent current-sense accuracy is maintained. The $\mathrm{R}_{\mathrm{DS} \text { (on) }}$ of the high-side transistors remain unchanged, see Table 5 DC Parameters for more details.

## PWM Current Control

A PWM comparator compares continuously the actual winding current with the requested current and feeds back the information to a digital regulation loop. This loop then generates a PWM signal, which turns on/off the H-bridge switches. The switching points of the PWM duty-cycle are synchronized to the on-chip PWM clock. The frequency of the PWM controller can be doubled and an artificial jitter can be added (see SPI Control Parameter Overview PWMJ). The PWM frequency will not vary with changes in the supply voltage. Also variations in motor-speed or load-conditions of the motor have no effect. There are no external components required to adjust the PWM frequency.

## Automatic Forward and Slow-Fast Decay

The PWM generation is in steady-state using a combination of forward and slow-decay. The absence of fast-decay in this mode, guarantees the lowest possible current-ripple "by design". For transients to lower current levels, fast-decay is automatically activated to allow high-speed response. The selection of fast or slow decay is completely transparent for the user and no additional parameters are required for operation.

Figure 8. Forward and Slow/Fast Decay PWM

## Automatic Duty Cycle Adaptation

In case the supply voltage is lower than $2 *$ Bemf, then the duty cycle of the PWM is adapted automatically to $>50 \%$ to maintain the requested average current in the coils. This
process is completely automatic and requires no additional parameters for operation. The over-all current-ripple is divided by two if PWM frequency is doubled (see SPI Control Parameter Overview PWMF).

Figure 9. Automatic Duty Cycle Adaptation

## Step Translator and Step Mode

The step translator provides the control of the motor by means of SPI register Stepmode: SM[2:0], SPI register DIRCNTRL, and input pins DIR and NXT. It is translating consecutive steps in corresponding currents in both motor coils for a given step mode.

One out of seven possible stepping modes can be selected through SPI-bits SM[2:0] (see SPI Control Parameter Overview). After power-on or hard reset, the coil-current translator is set to the default $1 / 32$ micro-stepping at position ' 0 '. Upon changing the step mode, the translator jumps to position $0^{*}$ of the corresponding stepping mode.

When remaining in the same step mode, subsequent translator positions are all in the same column and increased or decreased with 1 . Table 10 lists the output current versus the translator position.

As shown in Figure 10 the output current-pairs can be projected approximately on a circle in the ( $\mathrm{I}_{\mathrm{x}}, \mathrm{I}_{\mathrm{y}}$ ) plane. There are, however, two exceptions: uncompensated half step and full step. In these step modes the currents are not regulated to a fraction of $\mathrm{I}_{\text {max }}$ but are in all intermediate steps regulated at $100 \%$. In the $\left(\mathrm{I}_{\mathrm{x}}, \mathrm{I}_{\mathrm{y}}\right)$ plane the current-pairs are projected on a square. Table 9 lists the output current versus the translator position for these cases.

Table 9. SQUARE TRANSLATOR TABLE FOR FULL STEP AND UNCOMPENSATED HALF STEP

| MSP[6:0] | Stepmode ( SM[2:0]) |  | \% of $I_{\text {max }}$ |  |

Figure 10. Translator Table: Circular and Square

## Direction

The direction of rotation is selected by means of following combination of the DIR input pin and the SPI-controlled direction bit <DIRCTRL>. (see Table 14 SPI Control Parameter Overview)

## NXT Input

Changes on the NXT input will move the motor current one step up/down in the translator table (even when the motor is disabled <MOTEN>=0>). Depending on the

NXT-polarity bit <NXTP> (see Table 14 SPI Control Parameter Overview), the next step is initiated either on the rising edge or the falling edge of the NXT input.

## Translator Position

The translator position MSP[6:0] can be read in SPI Status Register 3 (See Table 15 SR3). This is a 7 -bit number equivalent to the $1 / 32^{\text {th }}$ micro-step from Table 10: Circular Translator Table. The translator position is updated immediately following a NXT trigger.

Figure 11. Translator Position Timing Diagram

## Synchronization of Step Mode and NXT Input

When step mode is re-programmed to another resolution (Figure 12), then this is put in effect immediately upon the first arriving "NXT" input. If the micro-stepping resolution is increased, the coil currents will be regulated to the nearest micro-step, according to the fixed grid of the increased resolution. If however the micro-stepping resolution is decreased, then it is possible to introduce an offset (or phase shift) in the micro-step translator table.

If the step resolution is decreased at a translator table position that is shared both by the old and new resolution setting, then the offset is zero and micro-stepping is proceeds according to the translator table.

If the translator position is not shared both by the old and new resolution setting, then the micro-stepping proceeds with an offset relative to the translator table (See Figure 12 right hand side).

Change from lower to higher resolution

Change from higher to lower resolution

Figure 12. NXT-Step Mode Synchronization
Left: Change from lower to higher resolution. The left-hand side depicts the ending half-step position during which a new step mode resolution was programmed. The right-hand side diagram shows the effect of subsequent NXT commands on the micro-step position.
Right: Change from higher to lower resolution. The left-hand side depicts the ending micro-step position during which a new step mode resolution was programmed. The right-hand side diagram shows the effect of subsequent NXT commands on the half-step position.
Note: It is advised to reduce the micro-stepping resolution only at micro-step positions that overlap with desired micro-step positions of the new resolution.

## Programmable Peak-Current

The amplitude of the current waveform in the motor coils (coil peak current $=I_{\text {max }}$ ) is adjusted by means of an SPI parameter "CUR[4:0]" (see Table 14 SPI Control Parameter

Overview). Whenever this parameter is changed, the coil-currents will be updated immediately at the next PWM period. Figure 13 presents the Peak-Current and Current Ratings in conjunction to the Current setting CUR[4:0].

Figure 13. Programmable Peak-Current Overview

## Speed and Load Angle Output

The SLA-pin provides an output voltage that indicates the level of the Back-e.m.f. voltage of the motor. This Back-e.m.f. voltage is sampled during every so-called "coil
current zero crossings". Per coil, two zero-current positions exist per electrical period, yielding in total four zero-current observation points per electrical period.

Figure 14. Principle of Bemf Measurement

Because of the relatively high recirculation currents in the coil during current decay, the coil voltage $\mathrm{V}_{\text {COIL }}$ shows a transient behavior. As this transient is not always desired in application software, two operating modes can be selected by means of the bit <SLAT> (see "SLA-transparency" in see SPI Control Parameter Overview). The SLA pin shows in "transparent mode" full visibility of the voltage transient behavior. This allows a sanity-check of the speed-setting versus motor operation and characteristics and supply voltage levels. If the bit "SLAT" is cleared, then only the voltage samples at the end of each coil current zero crossing are visible on the SLA-pin. Because the transient behavior
of the coil voltage is not visible anymore, this mode generates smoother Back e.m.f. input for post-processing, e.g. by software.

In order to bring the sampled Back e.m.f. to a descent output level $(0 \mathrm{~V}$ to 5 V$)$, the sampled coil voltage $\mathrm{V}_{\text {COIL }}$ is divided by 2 or by 4 . This divider is set through an SPI bit <SLAG>. (see SPI Control Parameter Overview)
The following drawing illustrates the operation of the SLA-pin and the transparency-bit. "PWMsh" and "I ${ }_{\text {COIL }}=$ $0 "$ are internal signals that define together with SLAT the sampling and hold moments of the coil voltage.

Figure 15. Timing Diagram of SLA-pin

## Warning, Error Detection and Diagnostics Feedback

## Thermal Warning and Shutdown

When junction temperature rises above $\mathrm{T}_{\mathrm{TW}}$, the thermal warning bit <TW> is set (Table 16 SPI Status registers Address SR0). If junction temperature increases above thermal shutdown level, then the circuit goes in "Thermal Shutdown" mode (<TSD>) and all driver transistors are disabled (high impedance) (see Table 16 SPI Status registers Address SR2). The conditions to reset flag <TSD> is to be at a temperature lower than $\mathrm{T}_{\mathrm{TW}}$ and to clear the $<\mathrm{TSD}>$ flag by reading it using any SPI read command.

## Overcurrent Detection

The overcurrent detection circuit monitors the load current in each activated output stage. If the load current exceeds the overcurrent detection threshold, then the over-current flag is set and the drivers are switched off to reduce the power dissipation and to protect the integrated circuit. Each driver transistor has an individual detection bit in (see Table 16 SPI Status registers Address SR1 and SR2: <OVCXij> and <OVCYij>). Error condition is latched and the microcontroller needs to clean the status bits to reactivate the drivers.

Note: Successive reading the SPI StatusRegisters 1 and 2 in case of a short circuit condition, may lead to damage to the drivers.

## Open Coil/Current Not Reached Detection

Open coil detection is based on the observation of $100 \%$ duty cycle of the PWM regulator. If in a coil $100 \%$ duty cycle is detected for longer than 200 ms then the related driver transistors are disabled (high-impedance) and an appropriate bit in the SPI status register is set (<OPENX> or <OPENY>). (Table 16)

When the resistance of a motor coil is very large and the supply voltage is low, it can happen that the motor driver is not able to deliver the requested current to the motor. Under these conditions the PWM controller duty cycle will be $100 \%$ and after 200 ms the error pin and <OPENX>, <OPENY> will flag this situation (motor current is kept alive). This feature can be used to test if the operating conditions (supply voltage, motor coil resistance) still allow reaching the requested coil-current or else the coil current should be reduced.

## Charge Pump Failure

The charge pump is an important circuit that guarantees low $\mathrm{R}_{\mathrm{DS}(o n)}$ for all drivers, especially for low supply
voltages. If supply voltage is too low or external components are not properly connected to guarantee $\mathrm{R}_{\mathrm{DS}(\text { on) }}$ of the drivers, then the bit <CPFAIL> is set (Table 16). Also after POR the charge pump voltage will need some time to exceed the required threshold. During that time $<$ CPFAIL $>$ will be set to " 1 ".

## Error Output

This is a digital output to flag a problem to the external microcontroller. The signal on this output is active low and the logic combination of:

```
NOT(ERRB) = <TW> OR <TSD> OR <OVCXij> OR
<OVCYij> OR <OPENi> OR <CPFAIL>
```

## Logic Supply Regulator

AMIS-30532 has an on-chip 5 V low-drop regulator with external capacitor to supply the digital part of the chip,
some low-voltage analog blocks and external circuitry. The voltage is derived from an internal bandgap reference. To calculate the available drive-current for external circuitry, the specified $\mathrm{I}_{\text {load }}$ should be reduced with the consumption of internal circuitry (unloaded outputs) and the loads connected to logic outputs. See Table 5 DC Parameters.

## Power-On Reset (POR) Function

The open drain output pin $\overline{\text { POR/WD provides an "active }}$ low" reset for external purposes. At power-up of AMIS-30532, this pin will be kept low for some time to reset for example an external microcontroller. A small analog filter avoids resetting due to spikes or noise on the $\mathrm{V}_{\mathrm{DD}}$ supply.

Figure 16. Power-on-Reset Timing Diagram

## Watchdog Function

The watchdog function is enabled/disabled through <WDEN> bit (Table 13: SPI CONTROL REGISTERS (ALL SPI control registers have Read/Write Access and default to " 0 " after power-on or hard reset.)). Once this bit has been set to " 1 " (watchdog enable), the microcontroller needs to re-write this bit to clear an internal timer before the watchdog timeout interval expires. In case the timer is activated and WDEN is acknowledged too early (before $t_{\text {WDPR }}$ ) or not within the interval (after $t_{\text {WDTO }}$ ), then a reset of the microcontroller will occur through $\overline{\mathrm{POR}} / \mathrm{WD}$ pin. In addition, a warm/cold boot bit <WD> is available (see Tables 16 and 17) for further processing when the external microcontroller is alive again.

## CLR Pin (=Hard Reset)

Logic 0 on CLR pin allows normal operation of the chip. To reset the complete digital inside AMIS-30532, the input CLR needs to be pulled to logic 1 during minimum time given by tclr. (Table 6 AC Parameters). This reset function clears all internal registers without the need of a power-cycle, except in sleep mode. The operation of all
analog circuits is depending on the reset state of the digital, charge pump remains active. Logic 0 on CLR pin resumes normal operation again.

The voltage regulator remains functional during and after the reset and the $\overline{\text { POR/WD pin is not activated. Watchdog }}$ function is reset completely.

## Sleep Mode

The bit <SLP> in SPI Control Register 2 (See Table 12) is provided to enter a so-called "sleep mode". This mode allows reduction of current-consumption when the motor is not in operation. The effect of sleep mode is as follows:

- The drivers are put in HiZ
- All analog circuits are disabled and in low-power mode
- All internal registers are maintaining their logic content
- NXT and DIR inputs are forbidden
- SPI communication remains possible (slight current increase during SPI communication)
- Reset of chip is possible through CLR pin
- Oscillator and digital clocks are silent, except during SPI communication
The voltage regulator remains active but with reduced current-output capability (I $\mathrm{I}_{\text {LOADSLP }}$ ). The watchdog timer stops running and it's value is kept in the counter. Upon
leaving sleep mode, this timer continues from the value it had before entering sleep mode.

Normal operation is resumed after writing logic ' 0 ' to bit <SLP>. A start-up time is needed for the charge pump to stabilize. After this time, NXT commands can be issued.

Figure 17. Watchdog Timing Diagram

Note: $t_{\text {DSPI }}$ is the time needed by the external microcontroller to shift-in the <WDEN> bit after a power-up.
The duration of the watchdog timeout interval is programmable through the WDT[3:0] bits (See also Table 13: SPI CONTROL REGISTERS (ALL SPI control registers have Read/Write Access and default to " 0 " after power-on or hard reset.). The timing is given in Table 12 below.

Table 12. WATCHDOG TIMEOUT INTERVAL AS FUNCTION OF WDT[3.0]

| Index WDT[3:0] |  | $\mathbf{t}_{\text {WDTO }}$ (ms) |  | Index WDT[3:0] |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0000 | 32 | 8 | 1000 | $\mathbf{t}_{\text {WDTO (ms) }}$ |
| 1 | 0001 | 64 | 9 | 1001 | 288 |
| 2 | 0010 | 96 | 10 | 1010 | 320 |
| 3 | 0011 | 128 | 11 | 1011 | 352 |
| 4 | 0100 | 160 | 12 | 1100 | 384 |
| 5 | 0101 | 192 | 13 | 1101 | 416 |

| 7 | 0111 | 256 | 15 | 1111 | 480 |

## SPI INTERFACE

The serial peripheral interface (SPI) allows an external microcontroller (Master) to communicate with AMIS-30532. The implemented SPI block is designed to interface directly with numerous micro-controllers from several manufacturers. AMIS-30532 acts always as a Slave and can't initiate any transmission. The operation of the device is configured and controlled by means of SPI registers which are observable for read and/or write from the Master.

## SPI Transfer Format and Pin Signals

During a SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line (CLK) synchronizes shifting and sampling of the information on the two serial data lines (DO and DI).

DO signal is the output from the Slave (AMIS-30532), and DI signal is the output from the Master. A chip select line ( $\overline{\mathrm{CS}}$ ) allows individual selection of a Slave SPI device in a multiple-slave system. The $\overline{\mathrm{CS}}$ line is active low. If AMIS-30532 is not selected, DO is pulled up with the external pull up resistor. Since AMIS-30532 operates as a Slave in MODE $0(\mathrm{CPOL}=0 ; \mathrm{CPHA}=0)$ it always clocks data out on the falling edge and samples data in on rising edge of clock. The Master SPI port must be configured in MODE 0 too, to match this operation. The SPI clock idles low between the transferred bytes.

The diagram below is both a Master and a Slave timing diagram since CLK, DO and DI pins are directly connected between the Master and the Slave.

NOTE: At the falling edge of the eight clock pulse the data-out shift register is updated with the content of the addressed internal SPI register. The internal SPI registers are updated at the first rising edge of the AMIS-30532 system clock when $\overline{\mathrm{CS}}=\mathrm{High}$

## Transfer Packet

Serial data transfer is assumed to follow MSB first rule. The transfer packet contains one or more 8-bit characters (bytes).

Figure 19. SPI Transfer Packet

Byte 1 contains the Command and the SPI Register Address and indicates to AMIS-30532 the chosen type of operation and addressed register. Byte 2 contains data, or
sent from the Master in a WRITE operation, or received from AMIS-30532 in a READ operation.

Two command types can be distinguished in the communication between master and AMIS-30532:

- READ from SPI Register with address ADDR[4:0]: CMD2 $=" 0 "$
- WRITE to SPI Register with address ADDR[4:0]: CMD2 = " 1 "

## READ Operation

If the Master wants to read data from Status or Control Registers, it initiates the communication by sending a

READ command. This READ command contains the address of the SPI register to be read out. At the falling edge of the eight clock pulse the data-out shift register is updated with the content of the corresponding internal SPI register. In the next 8 -bit clock pulse train this data is shifted out via DO pin. At the same time the data shifted in from DI (Master) should be interpreted as the following successive command or dummy data.

Figure 20. Single READ Operation where DATA from SPI register with Address 1 is read by the Master

All 4 Status Registers (see SPI Registers) contain 7 data bits and a parity check bit The most significant bit (D7) represents a parity of $\mathrm{D}[6: 0]$. If the number of logical ones in $\mathrm{D}[6: 0]$ is odd, the parity bit D 7 equals " 1 ". If the number of logical ones in $\mathrm{D}[6: 0]$ is even then the parity bit D 7 equals " 0 ". This simple mechanism protects against noise and increases the consistency of the transmitted data. If a parity check error occurs it is recommended to initiate an additional READ command to obtain the status again.

Also the Control Registers can be read out following the same routine. Control Registers don't have a parity check.

The $\overline{\mathrm{CS}}$ line is active low and may remain low between successive READ commands as illustrated in Figure 22. There is however one exception. In case an error condition is latched in one of Status Registers (see SPI Registers) the ERRB pin is activated. (See Section Error Output). This signal flags a problem to the external microcontroller. By reading the Status Registers information about the root cause of the problem can be determined. After this READ operation the Status Registers are cleared. Because the Status Registers and ERRB pin (see SPI Registers) are only updated by the internal system clock when the $\overline{\mathrm{CS}}$ line is
high, the Master should force $\overline{\mathrm{CS}}$ high immediately after the READ operation. For the same reason it is recommended to keep the $\overline{\mathrm{CS}}$ line high always when the SPI bus is idle.

## WRITE Operation

If the Master wants to write data to a Control Register it initiates the communication by sending a WRITE command. This contains the address of the SPI register to write to. The command is followed with a data byte. This incoming data will be stored in the corresponding Control Register after $\overline{\mathrm{CS}}$ goes from low to high! AMIS-30532 responds on every incoming byte by shifting out via DO the data stored in the last received address.

It is important that the writing action (command - address and data) to the Control Register is exactly 16 bits long. If more or less bits are transmitted the complete transfer packet is ignored.

A WRITE command executed for a read-only register (e.g. Status Registers) will not affect the addressed register and the device operation.

Because after a power-on-reset the initial address is unknown the data shifted out via DO is not valid.

AMIS-30532

Figure 21. Single WRITE Operation where DATA from the Master is written in SPI register with Address 3

## Examples of Combined READ and WRITE Operations

In the following examples successive READ and WRITE operations are combined. In Figure 22 the Master first reads the status from Register at ADDR4 and at ADDR5 followed
by writing a control byte in Control Register at ADDR2. Note that during the write command the old data of the pointed register is returned at the moment the new data is shifted in.

Figure 22. 2 Successive READ Commands Followed by a WRITE Command

After the write operation the Master could initiate a read back command in order to verify the data correctly written as illustrated in Figure 23. During reception of the READ command the old data is returned for a second time. Only after receiving the READ command the new data is
transmitted. This rule also applies when the master device wants to initiate an SPI transfer to read the Status Registers. Because the internal system clock updates the Status Registers only when $\overline{\mathrm{CS}}$ line is high, the first read out byte might represent old status information.

Figure 23. A WRITE Operation Where DATA from the Master is Written in SPI Register with Address 2 Followed by a READ Back Operation to Confirm a Correct WRITE Operation

NOTE: The internal data-out shift buffer of AMIS-30532 is updated with the content of the selected SPI register only at the last (every eight) falling edge of the CLK signal (see SPI Transfer Format and Pin Signals). As a result, new data for transmission cannot be written to the shift buffer at the beginning of the transfer packet and the first byte shifted out might represent old data.

Table 13. SPI CONTROL REGISTERS (All SPI control registers have Read/Write Access and default to " 0 " after power-on or hard reset)

| Address | Content | Structure |  |  |  |  |  |  |  |
