List of Registers

The Cortex-M4F Processor	62
Register 1: Cortex General-Purpose Register 0 (R0)	70
Register 2: Cortex General-Purpose Register 1 (R1)	70
Register 3: Cortex General-Purpose Register 2 (R2)	70
Register 4: Cortex General-Purpose Register 3 (R3)	70
Register 5: Cortex General-Purpose Register 4 (R4)	70
Register 6: Cortex General-Purpose Register 5 (R5)	70
Register 7: Cortex General-Purpose Register 6 (R6)	70
Register 8: Cortex General-Purpose Register 7 (R7)	70
Register 9: Cortex General-Purpose Register 8 (R8)	70
Register 10: Cortex General-Purpose Register 9 (R9)	70
Register 11: Cortex General-Purpose Register 10 (R10)	70
Register 12: Cortex General-Purpose Register 11 (R11)	70
Register 13: Cortex General-Purpose Register 12 (R12)	70
Register 14: Stack Pointer (SP)	71
Register 15: Link Register (LR)	72
Register 16: Program Counter (PC)	73
Register 17: Program Status Register (PSR)	74
Register 18: Priority Mask Register (PRIMASK)	78
Register 19: Fault Mask Register (FAULTMASK)	79
Register 20: Base Priority Mask Register (BASEPRI)	80
Register 21: Control Register (CONTROL)	81
Register 22: Floating-Point Status Control (FPSC)	83
Cortex-M4 Peripherals	116
Register 1: SysTick Control and Status Register (STCTRL), offset 0x010	132
Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014	134
Register 3: SysTick Current Value Register (STCURRENT), offset 0x018	135
Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100	136
Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104	136
Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108	136
Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C	136
Register 8: Interrupt 128-131 Set Enable (EN4), offset 0x110	137
Register 9: Interrupt 0-31 Clear Enable (DIS0), offset 0x180	138
Register 10: Interrupt 32-63 Clear Enable (DIS1), offset 0x184	138
Register 11: Interrupt 64-95 Clear Enable (DIS2), offset 0x188	138
Register 12: Interrupt 96-127 Clear Enable (DIS3), offset 0x18C	138
Register 13: Interrupt 128-131 Clear Enable (DIS4), offset 0x190	139
Register 14: Interrupt 0-31 Set Pending (PEND0), offset 0x200	140
Register 15: Interrupt 32-63 Set Pending (PEND1), offset 0x204	140
Register 16: Interrupt 64-95 Set Pending (PEND2), offset 0x208	140
Register 17: Interrupt 96-127 Set Pending (PEND3), offset 0x20C	140
Register 18: Interrupt 128-131 Set Pending (PEND4), offset 0x210	141
Register 19: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280	142
Register 20: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284	142
Register 21: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288	142

Register 22:	Interrupt 96-127 Clear Pending (UNPEND3), offset 0x28C	142
Register 23:	Interrupt 128-131 Clear Pending (UNPEND4), offset 0x290	143
Register 24:	Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300	144
Register 25:	Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304	144
Register 26:	Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308	144
Register 27:	Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C	144
Register 28:	Interrupt 128-131 Active Bit (ACTIVE4), offset 0x310	145
Register 29:	Interrupt 0-3 Priority (PRI0), offset 0x400	146
Register 30:	Interrupt 4-7 Priority (PRI1), offset 0x404	146
Register 31:	Interrupt 8-11 Priority (PRI2), offset 0x408	146
Register 32:	Interrupt 12-15 Priority (PRI3), offset 0x40C	146
Register 33:	Interrupt 16-19 Priority (PRI4), offset 0x410	146
Register 34:	Interrupt 20-23 Priority (PRI5), offset 0x414	146
Register 35:	Interrupt 24-27 Priority (PRI6), offset 0x418	146
Register 36:	Interrupt 28-31 Priority (PRI7), offset 0x41C	146
Register 37:	Interrupt 32-35 Priority (PRI8), offset 0x420	146
Register 38:	Interrupt 36-39 Priority (PRI9), offset 0x424	146
Register 39:	Interrupt 40-43 Priority (PRI10), offset 0x428	146
Register 40:	Interrupt 44-47 Priority (PRI11), offset 0x42C	146
Register 41:	Interrupt 48-51 Priority (PRI12), offset 0x430	146
Register 42:	Interrupt 52-55 Priority (PRI13), offset 0x434	146
Register 43:	Interrupt 56-59 Priority (PRI14), offset 0x438	146
Register 44:	Interrupt 60-63 Priority (PRI15), offset 0x43C	146
Register 45:	Interrupt 64-67 Priority (PRI16), offset 0x440	148
Register 46:	Interrupt 68-71 Priority (PRI17), offset 0x444	148
Register 47:	Interrupt 72-75 Priority (PRI18), offset 0x448	148
Register 48:	Interrupt 76-79 Priority (PRI19), offset 0x44C	148
Register 49:	Interrupt 80-83 Priority (PRI20), offset 0x450	148
Register 50:	Interrupt 84-87 Priority (PRI21), offset 0x454	148
Register 51:	Interrupt 88-91 Priority (PRI22), offset 0x458	148
Register 52:	Interrupt 92-95 Priority (PRI23), offset 0x45C	148
Register 53:	Interrupt 96-99 Priority (PRI24), offset 0x460	148
Register 54:	Interrupt 100-103 Priority (PRI25), offset 0x464	148
Register 55:	Interrupt 104-107 Priority (PRI26), offset 0x468	148
Register 56:	Interrupt 108-111 Priority (PRI27), offset 0x46C	148
Register 57:	Interrupt 112-115 Priority (PRI28), offset 0x470	148
Register 58:	Interrupt 116-119 Priority (PRI29), offset 0x474	148
Register 59:	Interrupt 120-123 Priority (PRI30), offset 0x478	148
Register 60:	Interrupt 124-127 Priority (PRI31), offset 0x47C	148
Register 61:	Interrupt 128-131 Priority (PRI32), offset 0x480	148
Register 62:	Software Trigger Interrupt (SWTRIG), offset 0xF00	150
Register 63:	Auxiliary Control (ACTLR), offset 0x008	151
Register 64:	CPU ID Base (CPUID), offset 0xD00	153
Register 65:	Interrupt Control and State (INTCTRL), offset 0xD04	154
Register 66:	Vector Table Offset (VTABLE), offset 0xD08	157
Register 67:	Application Interrupt and Reset Control (APINT), offset 0xD0C	158
Register 68:	System Control (SYSCTRL), offset 0xD10	160
Register 69:	Configuration and Control (CFGCTRL), offset 0xD14	162

Register 70:	System Handler Priority 1 (SYSPRI1), offset 0xD18	164
Register 71:	System Handler Priority 2 (SYSPRI2), offset 0xD1C	165
Register 72:	System Handler Priority 3 (SYSPRI3), offset 0xD20	166
Register 73:	System Handler Control and State (SYSHNDCTRL), offset 0xD24	167
Register 74:	Configurable Fault Status (FAULTSTAT), offset 0xD28	171
Register 75:	Hard Fault Status (HFAULTSTAT), offset 0xD2C	177
Register 76:	Memory Management Fault Address (MMADDR), offset 0xD34	178
Register 77:	Bus Fault Address (FAULTADDR), offset 0xD38	179
Register 78:	MPU Type (MPUTYPE), offset 0xD90	180
Register 79:	MPU Control (MPUCTRL), offset 0xD94	181
Register 80:	MPU Region Number (MPUNUMBER), offset 0xD98	183
Register 81:	MPU Region Base Address (MPUBASE), offset 0xD9C	184
Register 82:	MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4	184
Register 83:	MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC	184
Register 84:	MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4	184
Register 85:	MPU Region Attribute and Size (MPUATTR), offset 0xDA0	186
Register 86:	MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8	186
Register 87:	MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0	186
Register 88:	MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8	186
Register 89:	Coprocessor Access Control (CPAC), offset 0xD88	189
Register 90:	Floating-Point Context Control (FPCC), offset 0xF34	190
Register 91:	Floating-Point Context Address (FPCA), offset 0xF38	192
Register 92:	Floating-Point Default Status Control (FPDSC), offset 0xF3C	193
System Control		206
Register 1:	Device Identification 0 (DID0), offset 0x000	229
Register 2:	Device Identification 1 (DID1), offset 0x004	231
Register 3:	Device Capabilities 0 (DC0), offset 0x008	233
Register 4:	Device Capabilities 1 (DC1), offset 0x010	234
Register 5:	Device Capabilities 2 (DC2), offset 0x014	237
Register 6:	Device Capabilities 3 (DC3), offset 0x018	240
Register 7:	Device Capabilities 4 (DC4), offset 0x01C	244
Register 8:	Device Capabilities 5 (DC5), offset 0x020	247
Register 9:	Device Capabilities 6 (DC6), offset 0x024	249
Register 10:	Device Capabilities 7 (DC7), offset 0x028	250
Register 11:	Device Capabilities 8 (DC8), offset 0x02C	253
Register 12:	Brown-Out Reset Control (PBORCTL), offset 0x030	256
Register 13:	Software Reset Control 0 (SRCR0), offset 0x040	257
Register 14:	Software Reset Control 1 (SRCR1), offset 0x044	259
Register 15:	Software Reset Control 2 (SRCR2), offset 0x048	262
Register 16:	Raw Interrupt Status (RIS), offset 0x050	264
Register 17:	Interrupt Mask Control (IMC), offset 0x054	266
Register 18:	Masked Interrupt Status and Clear (MISC), offset 0x058	268
Register 19:	Reset Cause (RESC), offset 0x05C	270
Register 20:	Run-Mode Clock Configuration (RCC), offset 0x060	272
Register 21:	GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C	276
Register 22:	Run-Mode Clock Configuration 2 (RCC2), offset 0x070	278
Register 23:	Main Oscillator Control (MOSCCTL), offset 0x07C	281
Register 24:	Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100	282

Register 25:	Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104	285
Register 26:	Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108	289
Register 27:	Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110	292
Register 28:	Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114	295
Register 29:	Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118	299
Register 30:	Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120	302
Register 31:	Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124	305
Register 32:	Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128	309
Register 33:	Deep Sleep Clock Configuration (DSLPCCLKCFG), offset 0x144	312
Register 34:	System Properties (SYSPROP), offset 0x14C	314
Register 35:	Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150	315
Register 36:	Precision Internal Oscillator Statistics (PIOSCSTAT), offset 0x154	317
Register 37:	PLL Frequency 0 (PLLREQ0), offset 0x160	318
Register 38:	PLL Frequency 1 (PLLREQ1), offset 0x164	319
Register 39:	PLL Status (PLLSTAT), offset 0x168	320
Register 40:	Device Capabilities 9 (DC9), offset 0x190	321
Register 41:	Non-Volatile Memory Information (NVMSTAT), offset 0x1A0	323
Register 42:	Watchdog Timer Peripheral Present (PPWD), offset 0x300	324
Register 43:	16/32-Bit General-Purpose Timer Peripheral Present (PPTIMER), offset 0x304	325
Register 44:	General-Purpose Input/Output Peripheral Present (PPGPIO), offset 0x308	327
Register 45:	Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C	330
Register 46:	Hibernation Peripheral Present (PPHIB), offset 0x314	331
Register 47:	Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset 0x318	332
Register 48:	Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C	334
Register 49:	Inter-Integrated Circuit Peripheral Present (PPI2C), offset 0x320	336
Register 50:	Universal Serial Bus Peripheral Present (PPUSB), offset 0x328	338
Register 51:	Controller Area Network Peripheral Present (PPCAN), offset 0x334	339
Register 52:	Analog-to-Digital Converter Peripheral Present (PPADC), offset 0x338	340
Register 53:	Analog Comparator Peripheral Present (PPACMP), offset 0x33C	341
Register 54:	Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340	342
Register 55:	Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344	343
Register 56:	EEPROM Peripheral Present (PPEEPROM), offset 0x358	344
Register 57:	32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER), offset 0x35C	345
Register 58:	Watchdog Timer Software Reset (SRWD), offset 0x500	347
Register 59:	16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504	349
Register 60:	General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508	351
Register 61:	Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C	354
Register 62:	Hibernation Software Reset (SRHIB), offset 0x514	355
Register 63:	Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518	356
Register 64:	Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C	358
Register 65:	Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520	360
Register 66:	Universal Serial Bus Software Reset (SRUSB), offset 0x528	362
Register 67:	Controller Area Network Software Reset (SRCAN), offset 0x534	363
Register 68:	Analog-to-Digital Converter Software Reset (SRADC), offset 0x538	365
Register 69:	Analog Comparator Software Reset (SRACMP), offset 0x53C	367
Register 70:	EEPROM Software Reset (SREEEPROM), offset 0x558	368
Register 71:	32/64-Bit Wide General-Purpose Timer Software Reset (SRWTIMER), offset 0x55C	369

Register 72:	Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600	371

Revision History

The revision history table notes changes made between the indicated revisions of the LM4F120B2QR data sheet.

Table 1. Revision History

Date	Revision	Description
September 2011	10502	Started tracking revision history.

About This Document

This data sheet provides reference information for the LM4F120B2QR microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M4F core.

Audience

This manual is intended for system software developers, hardware designers, and application developers.

About This Manual

This document is organized into sections that correspond to each major feature.

Documentation Conventions

This document uses the conventions shown in Table 2 on page 36.

Table 2. Documentation Conventions

Notation	Meaning
General Register Notation	
REGISTER	APB registers are indicated in uppercase bold. For example, PBORCTL is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, SRCRn represents any (or all) of the three Software Reset Control registers: SRCR0 , SRCR1 , and SRCR2 .
bit	A single bit in a register.
bit field	Two or more consecutive and related bits.
offset 0xnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 85.
Register N	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
yy:xx	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.
Register Bit/Field Types	
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.
RO	Software can read this field. Always write the chip reset value.
R/W	Software can read or write this field.
R/WC	Software can read or write this field. Writing to it with any value clears the register.
R/W1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.
R/W1S	Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.
WO	Only a write by software is valid; a read of the register returns no meaningful data.
Register Bit/Field Reset Value	
0	Bit cleared to 0 on chip reset.
1	Bit set to 1 on chip reset.
-	Nondeterministic.
Pin/Signal Notation	
[]	Pin alternate function; a pin defaults to the signal without the brackets.
pin	Refers to the physical connection on the package.
signal	Refers to the electrical signal encoding of a pin.

Table 2. Documentation Conventions (continued)

Notation	Meaning
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see <code>SIGNAL</code> and <code>$\overline{\text{SIGNAL}}$</code> below).
deassert a signal	Change the value of the signal from the logically True state to the logically False state.
<code>$\overline{\text{SIGNAL}}$</code>	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert <code>$\overline{\text{SIGNAL}}$</code> is to drive it Low; to deassert <code>$\overline{\text{SIGNAL}}$</code> is to drive it High.
<code>SIGNAL</code>	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert <code>SIGNAL</code> is to drive it High; to deassert <code>SIGNAL</code> is to drive it Low.
Numbers	
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.

1 Architectural Overview

Texas Instruments is the industry leader in bringing 32-bit capabilities and the full benefits of ARM® Cortex™-M-based microcontrollers to the broadest reach of the microcontroller market. For current users of 8- and 16-bit MCUs, Stellaris® with Cortex-M offers a direct path to the strongest ecosystem of development tools, software and knowledge in the industry. Designers who migrate to Stellaris benefit from great tools, small code footprint and outstanding performance. Even more important, designers can enter the ARM ecosystem with full confidence in a compatible roadmap from \$1 to 1 GHz. With blazingly-fast responsiveness, Thumb-2 technology combines both 16-bit and 32-bit instructions to deliver the best balance of code density and performance. Thumb-2 uses 26 percent less memory than pure 32-bit code to reduce system cost while delivering 25 percent better performance. The Texas Instruments Stellaris family of microcontrollers brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

1.1 Stellaris LM4F Series Overview

The Stellaris LM4F series of ARM Cortex-M4 microcontrollers provides a wide range of capabilities and peripherals. The series encompasses categories of applications that include General MCU, USB, and Advanced Motion Control, with a generous number of serial communication peripherals, including up to 8 UARTs, 6 I²C, 4 SSI/SPI, and 2 CAN controllers.

Figure 1-1. Stellaris LM4F Block Diagram

The Stellaris LM4F microcontrollers consist of twelve pin-compatible series of devices, summarized below. Each series has a range of embedded flash and SRAM sizes.

Table 1-1. Stellaris LM4F Device Series

General MCU (LM4F110 Series)	General MCU + USB Device (LM4F120 Series)	General MCU + USB OTG (LM4F130 Series)	Motion Control + USB OTG (LM4F230 Series)	Package
LM4F110	LM4F120	LM4F130	LM4F230	64-pin LQFP
LM4F111	LM4F121	LM4F131	LM4F231	64-pin LQFP
LM4F112	LM4F122	LM4F132	LM4F232	100-pin LQFP 144-pin LQFP

The Stellaris LM4F120 Series for general MCU control applications with USB Device provides USB Device capability and a generous number of serial peripherals in three packages.

Table 1-2. Stellaris LM4F120 Series

Part Number	Flash (KB)	SRAM (KB)	5-V Tolerant GPIOs	Package	Notes
LM4F120B2QR	32	12	43	64-pin LQFP	Includes low-power hibernate functionality.
LM4F120C4QR	64	24			
LM4F120E5QR	128	32			
LM4F120H5QR	256	32			
LM4F121B2QR	32	12	49	64-pin LQFP	No low-power hibernate functionality, but includes additional serial functionality, and up to six more I/Os than the LM4F120 Series.
LM4F121C4QR	64	24			
LM4F121E5QR	128	32			
LM4F121H5QR	256	32			
LM4F122C4QC	64	24	69	100-pin LQFP	Includes low-power hibernate functionality, additional serial and analog functionality, and up to 20 more I/Os (56 for the 144LQFP) than the LM4F121 Series.
LM4F122E5QC	128	32			
LM4F122H5QC	256	32			
LM4F122H5QD	256	32	105	144-pin LQFP

a. USB options for Stellaris microcontrollers include Device Only (D) capability, Host/Device (H) capability, and On-The-Go/Host/Device capability (O).

b. Minimum is number of pins dedicated to GPIO; additional pins are available if certain peripherals are not used. See data sheet for details.

1.2 LM4F120B2QR Microcontroller Features

The LM4F120B2QR microcontroller has the following features:

- ARM Cortex-M4F Processor Core
 - 80-MHz operation; 100 DMIPS performance

- ARM Cortex SysTick Timer
- Nested Vectored Interrupt Controller (NVIC)
- Wake-Up Interrupt Controller (WIC) with clock gating
- Embedded Trace Macro and Trace Port
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- On-Chip Memory
 - 32 KB single-cycle Flash memory up to 40 MHz; a prefetch buffer improves performance above 40 MHz
 - 12 KB single-cycle SRAM
 - Internal ROM loaded with StellarisWare® software:
 - Stellaris Peripheral Driver Library
 - Stellaris Boot Loader
 - Advanced Encryption Standard (AES) cryptography tables
 - Cyclic Redundancy Check (CRC) error detection functionality
 - 2KB EEPROM
- Advanced Serial Integration
 - CAN 2.0 A/B controller
 - USB 2.0 Device
 - Eight UARTs with IrDA, 9-bit and ISO 7816 support (one UART with modem flow control)
 - Four I²C modules
 - Four Synchronous Serial Interface modules (SSI)
- System Integration
 - Direct Memory Access Controller (DMA)
 - System control and clocks including on-chip precision 16-MHz oscillator
 - Six 32-bit timers (up to twelve 16-bit)
 - Six wide 64-bit timers (up to twelve 32-bit)
 - Twelve 16/32-bit Capture Compare PWM (CCP) pins
 - Twelve 32/64-bit Capture Compare PWM (CCP) pins
 - Lower-power battery-backed Hibernation module
 - Real-Time Clock in Hibernation module
 - Two Watchdog Timers

- One timer runs off the main oscillator
- One timer runs off the precision internal oscillator
- Up to 43 GPIOs, depending on configuration
 - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
 - Independently configurable to 2, 4 or 8 mA drive capability
 - Up to 4 GPIOs can have 18 mA drive capability
- Analog
 - Two 12-bit Analog-to-Digital Converters (ADC) with 12 analog input channels and a sample rate of one million samples/second
 - Two analog comparators
 - 16 digital comparators
 - On-chip voltage regulator
- JTAG and ARM Serial Wire Debug (SWD)
- 64-pin LQFP package
- Industrial (-40°C to 85°C) temperature range

The LM4F120B2QR microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, transportation, and fire and security.

For applications requiring extreme conservation of power, the LM4F120B2QR microcontroller features a battery-backed Hibernation module to efficiently power down the LM4F120B2QR to a low-power state during extended periods of inactivity. With a power-up/power-down sequencer, a continuous time counter (RTC), a pair of match registers, an APB interface to the system bus, and dedicated battery-backed memory, the Hibernation module positions the LM4F120B2QR microcontroller perfectly for battery applications.

In addition, the LM4F120B2QR microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM4F120B2QR microcontroller is code-compatible to all members of the extensive Stellaris family; providing flexibility to fit our customers' precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network. See "Ordering and Contact Information" on page 1229 for ordering information for Stellaris family devices.

1.3 Functional Overview

The following sections provide an overview of the features of the LM4F120B2QR microcontroller. The page number in parentheses indicates where that feature is discussed in detail. Ordering and support information can be found in "Ordering and Contact Information" on page 1229.

1.3.1 ARM Cortex-M4F

The following sections provide an overview of the ARM Cortex-M4 processor core and instruction set, the integrated System Timer (SysTick), the Nested Vectored Interrupt Controller, the Memory Protection Unit (MPU), the Floating-Point Unit (FPU), and the System Control Block (SCB).

1.3.1.1 Processor Core (see page 62)

All members of the Stellaris product family, including the LM4F120B2QR microcontroller, are designed around an ARM Cortex-M4F processor core. The ARM Cortex-M4F processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

- 32-bit ARM Cortex-M4F architecture optimized for small-footprint embedded applications
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
 - Single-cycle multiply instruction and hardware divide
 - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
 - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7 processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage

- Ultra-low power consumption with integrated sleep modes
- 80-MHz operation
- 1.25 DMIPS/MHz

1.3.1.2 Memory Map (see page 85)

A memory map lists the location of instructions and data in memory. The memory map for the LM4F120B2QR controller can be found in “Memory Model” on page 85. Register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map.

1.3.1.3 System Timer (SysTick) (see page 117)

ARM Cortex-M4F includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations.

1.3.1.4 Nested Vectored Interrupt Controller (NVIC) (see page 118)

The LM4F120B2QR controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4F prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 65 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

1.3.1.5 System Control Block (SCB) (see page 119)

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

1.3.1.6 Memory Protection Unit (MPU) (see page 119)

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

1.3.1.7 Floating-Point Unit (FPU) (see page 124)

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined Multiply and Accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

1.3.2 On-Chip Memory

The following sections describe the on-chip memory modules.

1.3.2.1 SRAM (see page 526)

The LM4F120B2QR microcontroller provides 12 KB of single-cycle on-chip SRAM. The internal SRAM of the Stellaris devices is located at offset 0x2000.0000 of the device memory map.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the Cortex-M4F processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from the SRAM using the Micro Direct Memory Access Controller (μ DMA).

1.3.2.2 Flash Memory (see page 529)

The LM4F120B2QR microcontroller provides 32 KB of single-cycle on-chip Flash memory (above 40 MHz, the Flash memory can be accessed in a single cycle as long as the code is linear; branches incur a one-cycle stall). The Flash memory is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

1.3.2.3 ROM (see page 527)

The LM4F120B2QR ROM is preprogrammed with the following software and programs:

- Stellaris Peripheral Driver Library

- Stellaris Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The Stellaris Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM Cortex-M4F core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on lesser general public license (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

1.3.2.4 EEPROM (see page 532)

The LM4F120B2QR microcontroller includes an EEPROM with the following features:

- 2K bytes of memory accessible as 512 32-bit words
- 32 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages) per each 2-page block.

1.3.3 Serial Communications Peripherals

The LM4F120B2QR controller supports both asynchronous and synchronous serial communications with:

- CAN 2.0 A/B controller

- USB 2.0 Device
- Eight UARTs with IrDA, 9-bit and ISO 7816 support (one UART with modem flow control)
- Four I²C modules
- Four Synchronous Serial Interface modules (SSI)

The following sections provide more detail on each of these communications functions.

1.3.3.1 Controller Area Network (see page 1021)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The LM4F120B2QR microcontroller includes one CAN unit with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN_nTX and CAN_nRX signals

1.3.3.2 USB (see page 1071)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The LM4F120B2QR microcontroller supports the USB 2.0 full-speed configuration in Device mode.

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints

- 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
- 7 configurable IN endpoints and 7 configurable OUT endpoints
- 2 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size if it is the only endpoint used
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
 - Channel requests asserted when FIFO contains required amount of data

1.3.3.3 UART (see page 872)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM4F120B2QR microcontroller includes eight fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem flow control, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The eight UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 μ s) bit durations

- Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem flow control (on UART1)
- LIN protocol support
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
 - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

1.3.3.4 I²C (see page 978)

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I²C bus interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I²C bus can be designated as either a master or a slave. I²C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I²C master and slave can generate interrupts.

The LM4F120B2QR microcontroller includes four I²C modules with the following features:

- Devices on the I²C bus can be designated as either a master or a slave
 - Supports both transmitting and receiving data as either a master or a slave
 - Supports simultaneous master and slave operation
- Four I²C modes
 - Master transmit
 - Master receive
 - Slave transmit
 - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Clock low timeout interrupt

- Dual slave address capability
- Master and slave interrupt generation
 - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
 - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

1.3.3.5 SSI (see page 935)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface that converts data between parallel and serial. The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The LM4F120B2QR microcontroller includes four SSI modules with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
 - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

1.3.4 System Integration

The LM4F120B2QR microcontroller provides a variety of standard system functions integrated into the device, including:

- Direct Memory Access Controller (DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- Six 32-bit timers (up to twelve 16-bit)
- Six wide 64-bit timers (up to twelve 32-bit)
- Twelve 16/32-bit Capture Compare PWM (CCP) pins
- Twelve 32/64-bit Capture Compare PWM (CCP) pins
- Lower-power battery-backed Hibernation module
- Real-Time Clock in Hibernation module
- Two Watchdog Timers
 - One timer runs off the main oscillator
 - One timer runs off the precision internal oscillator
- Up to 43 GPIOs, depending on configuration
 - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
 - Independently configurable to 2, 4 or 8 mA drive capability
 - Up to 4 GPIOs can have 18 mA drive capability

The following sections provide more detail on each of these functions.

1.3.4.1 Direct Memory Access (see page 581)

The LM4F120B2QR microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μ DMA). The μ DMA controller provides a way to offload data transfer tasks from the Cortex-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The μ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable μ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
 - Basic for simple transfer scenarios
 - Ping-pong for continuous data flow
 - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
 - Independently configured and operated channels
 - Dedicated channels for supported on-chip modules
 - Flexible channel assignments

- One channel each for receive and transmit path for bidirectional modules
- Dedicated channel for software-initiated transfers
- Per-channel configurable priority scheme
- Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between μ DMA controller and the processor core
 - μ DMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

1.3.4.2 System Control and Clocks (see page 206)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
 - On-chip fixed Low Drop-Out (LDO) voltage regulator
 - Hibernation module handles the power-up/down 3.3 V sequencing and control for the core digital logic and analog circuits
 - Low-power options for microcontroller: Sleep and Deep-sleep modes with clock gating
 - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
 - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock
 - Precision Oscillator (PIOSC): On-chip resource providing a 16 MHz \pm 1% frequency at room temperature
 - 16 MHz \pm 3% across temperature

- Can be recalibrated with 7-bit trim resolution
- Software power down control for low power modes
- Main Oscillator (MOSC): A frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.
 - External crystal used with or without on-chip PLL: select supported frequencies from 4 MHz to 25 MHz.
 - External oscillator: from DC to maximum device speed
- Internal 30-kHz Oscillator: on chip resource providing a 30 kHz \pm 50% frequency, used during power-saving modes
- 32.768-kHz external oscillator for the Hibernation Module: eliminates need for additional crystal for main clock source
- Flexible reset sources
 - Power-on reset (POR)
 - Reset pin assertion
 - Brown-out reset (BOR) detector alerts to system power drops
 - Software reset
 - Watchdog timer reset
 - MOSC failure

1.3.4.3 Programmable Timers (see page 700)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each 16/32-bit GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Each 32/64-bit Wide GPTM block provides two 32-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 64-bit timer or one 64-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

The General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks with the following functional options:

- 16/32-bit operating modes:
 - 16- or 32-bit programmable one-shot timer
 - 16- or 32-bit programmable periodic timer
 - 16-bit general-purpose timer with an 8-bit prescaler
 - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler

- 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- 32/64-bit operating modes:
 - 32- or 64-bit programmable one-shot timer
 - 32- or 64-bit programmable periodic timer
 - 32-bit general-purpose timer with a 16-bit prescaler
 - 64-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 32-bit input-edge count- or time-capture modes with a 16-bit prescaler
 - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Twelve 32/64-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each timer
 - Burst request generated on timer interrupt

1.3.4.4 CCP Pins (see page 707)

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The LM4F120B2QR microcontroller includes twelve 16/32-bit CCP pins and twelve 32/64-bit CCP pins that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.

- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

1.3.4.5 Hibernation Module (see page 495)

The Hibernation module provides logic to switch power off to the main processor and peripherals and to wake on external or time-based events. The Hibernation module includes power-sequencing logic and has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution
 - 32-bit RTC seconds match register and 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
 - RTC predivider trim for making fine adjustments to the clock rate
- Two mechanisms for power control
 - System power control using discrete external regulator
 - On-chip power control using internal switches under register control
- Dedicated pin for waking using an external signal
- RTC operational and hibernation memory valid as long as V_{BAT} is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from a 32.768-kHz external crystal or oscillator
- 16 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for RTC match, external wake, and low battery events

1.3.4.6 Watchdog Timers (see page 768)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The Stellaris Watchdog Timer can generate an interrupt, a non-maskable interrupt, or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the microcontroller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The LM4F120B2QR microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Stellaris Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function

- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

1.3.4.7 Programmable GPIOs (see page 645)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The Stellaris GPIO module is comprised of six physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FIRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-43 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 1145 for the signals available to each GPIO pin).

- Up to 43 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant in input configuration
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code for Ports A-H and J; Ports K-N and P-Q are accessed through the AHB
- Fast toggle capable of a change every clock cycle for ports on AHB, every two clock cycles for ports on APB
- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
 - Per-pin interrupts available on Port P and Port Q
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a μ DMA transfer
- Pin state can be retained during Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
 - Slew rate control for the 8-mA drive
 - Open drain enables

- Digital input enables

1.3.5 Analog

The LM4F120B2QR microcontroller provides analog functions integrated into the device, including:

- Two 12-bit Analog-to-Digital Converters (ADC) with 12 analog input channels and a sample rate of one million samples/second
- Two analog comparators
- 16 digital comparators
- On-chip voltage regulator

The following provides more detail on these analog functions.

1.3.5.1 ADC (see page 793)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The Stellaris ADC module features 12-bit conversion resolution and supports 12 input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to 12 analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. Each ADC module has a digital comparator function that allows the conversion value to be diverted to a comparison unit that provides eight digital comparators.

The LM4F120B2QR microcontroller provides two ADC modules with the following features:

- 12 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - GPIO
- Hardware averaging of up to 64 samples
- Digital comparison unit providing eight digital comparators

- Converter uses a VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each sample sequencer
 - ADC module uses burst requests for DMA

1.3.5.2 Analog Comparators (see page 1129)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The LM4F120B2QR microcontroller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The LM4F120B2QR microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
 - An individual external reference voltage
 - A shared single external reference voltage
 - A shared internal reference voltage

1.3.6 JTAG and ARM Serial Wire Debug (see page 194)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system memory without halting the core or requiring any target resident code. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTTEST
- ARM additional instructions: APACC, DPACC and ABORT

- Integrated ARM Serial Wire Debug (SWD)
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Embedded Trace Macrocell (ETM) for instruction trace capture
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

1.3.7 Packaging and Temperature

- Industrial-range 64-pin RoHS-compliant LQFP package

1.4 Target Applications

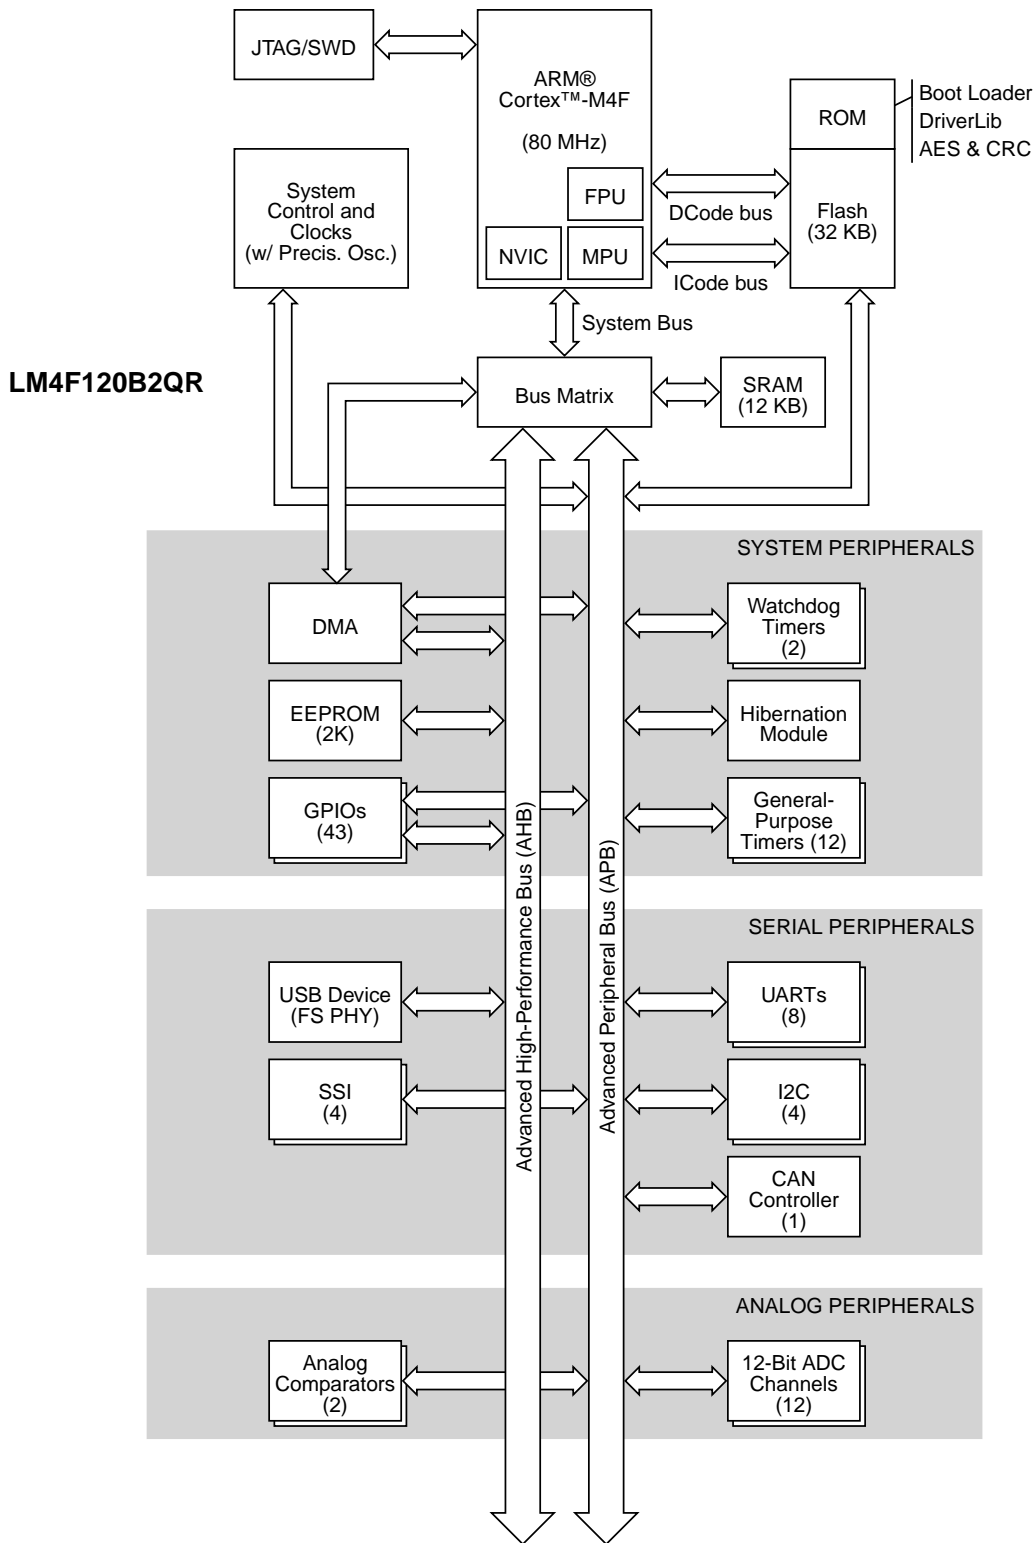

The Stellaris family is positioned for cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Test and measurement equipment
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy
- Transportation

1.5 High-Level Block Diagram

Figure 1-2 on page 60 depicts the features on the Stellaris LM4F120B2QR microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-2. Stellaris LM4F120B2QR Microcontroller High-Level Block Diagram

1.6 Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 1144
- “Signal Tables” on page 1145
- “Operating Characteristics” on page 1166
- “Electrical Characteristics” on page 1167
- “Package Information” on page 1231

2 The Cortex-M4F Processor

The ARM® Cortex™-M4F processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M4F architecture optimized for small-footprint embedded applications
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
 - Single-cycle multiply instruction and hardware divide
 - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
 - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7 processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage
- Ultra-low power consumption with integrated sleep modes
- 80-MHz operation
- 1.25 DMIPS/MHz

The Stellaris® family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motor control.

This chapter provides information on the Stellaris implementation of the Cortex-M4F processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the *ARM® Cortex™-M4 Technical Reference Manual*.

2.1 Block Diagram

The Cortex-M4F processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4F processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4F processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4F instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4F processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The Stellaris NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

Figure 2-1. CPU Block Diagram

2.2 Overview

2.2.1 System-Level Interface

The Cortex-M4F processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M4F processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

2.2.2 Integrated Configurable Debug

The Cortex-M4F processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Stellaris implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Embedded Trace Macrocell (ETM) delivers unrivaled instruction trace capture in an area smaller than traditional trace units, enabling full instruction trace. For more details on the ARM ETM, see the *ARM® Embedded Trace Macrocell Architecture Specification*.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions of up to eight words in the program code in the CODE memory region. This enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M4F debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M4F trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 65.

Figure 2-2. TPIU Block Diagram

2.2.4 Cortex-M4F System Component Details

The Cortex-M4F includes the following system components:

- SysTick

A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 117).

- Nested Vectored Interrupt Controller (NVIC)

An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 118).

- System Control Block (SCB)

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 119).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 119).

- Floating-Point Unit (FPU)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square-root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

2.3 Programming Model

This section describes the Cortex-M4F programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M4F has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M4F has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the `MSR` and `MRS` instructions and no use of the `CPS` instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 81) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the `SVC` instruction to make a supervisor call to transfer control to privileged software.

2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks: the main stack and the process stack, with a pointer for each held in independent registers (see the **SP** register on page 71).

In Thread mode, the **CONTROL** register (see page 81) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 67.

Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use

Processor Mode	Use	Privilege Level	Stack Used
Thread	Applications	Privileged or unprivileged ^a	Main stack or process stack ^a
Handler	Exception handlers	Always privileged	Main stack

a. See **CONTROL** (page 81).

2.3.3 Register Map

Figure 2-3 on page 68 shows the Cortex-M4F register set. Table 2-2 on page 68 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

Figure 2-3. Cortex-M4F Register Set

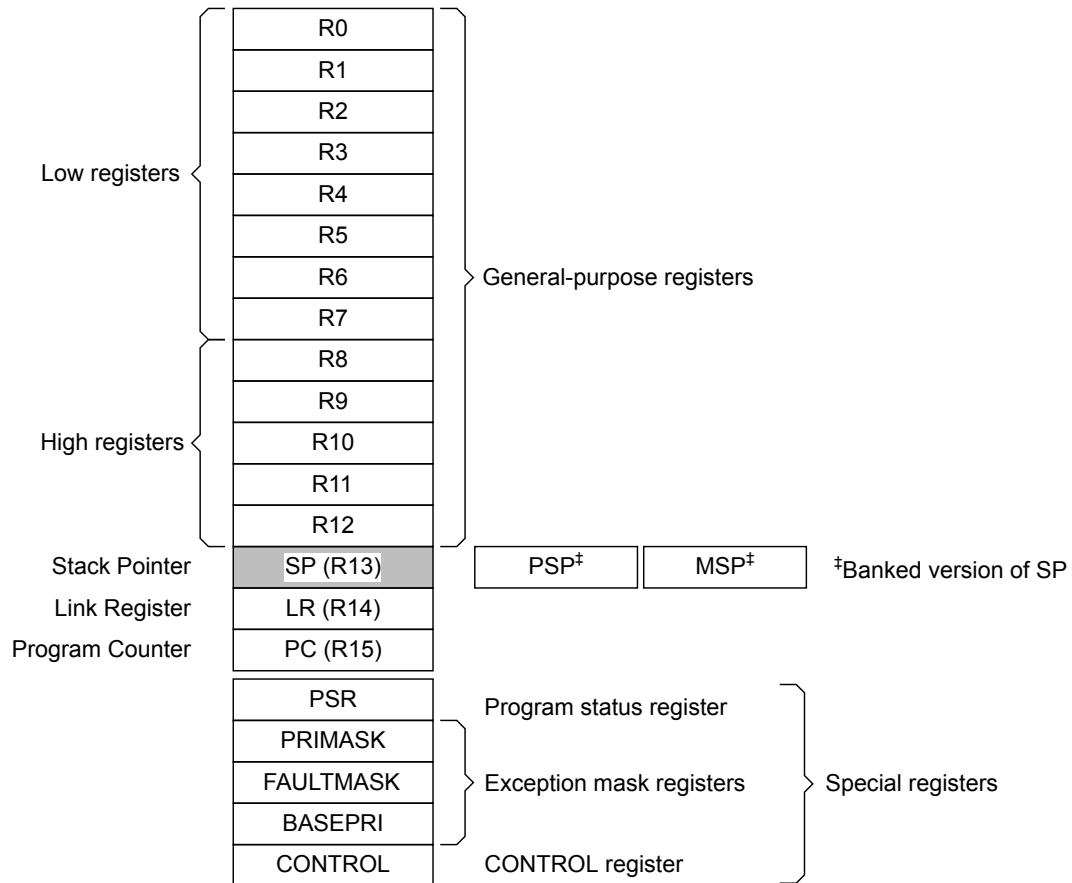

Table 2-2. Processor Register Map

Offset	Name	Type	Reset	Description	See page
-	R0	R/W	-	Cortex General-Purpose Register 0	70
-	R1	R/W	-	Cortex General-Purpose Register 1	70
-	R2	R/W	-	Cortex General-Purpose Register 2	70
-	R3	R/W	-	Cortex General-Purpose Register 3	70
-	R4	R/W	-	Cortex General-Purpose Register 4	70
-	R5	R/W	-	Cortex General-Purpose Register 5	70
-	R6	R/W	-	Cortex General-Purpose Register 6	70
-	R7	R/W	-	Cortex General-Purpose Register 7	70
-	R8	R/W	-	Cortex General-Purpose Register 8	70

-	CONTROL	R/W	0x0000.0000	Control Register	81
-	FPSC	R/W	-	Floating-Point Status Control	83

2.3.4 Register Descriptions

This section lists and describes the Cortex-M4F registers, in the order shown in Figure 2-3 on page 68. The core registers are not memory mapped and are accessed by register name rather than offset.

Note: The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

- Register 1: Cortex General-Purpose Register 0 (R0)**
- Register 2: Cortex General-Purpose Register 1 (R1)**
- Register 3: Cortex General-Purpose Register 2 (R2)**
- Register 4: Cortex General-Purpose Register 3 (R3)**
- Register 5: Cortex General-Purpose Register 4 (R4)**
- Register 6: Cortex General-Purpose Register 5 (R5)**
- Register 7: Cortex General-Purpose Register 6 (R6)**
- Register 8: Cortex General-Purpose Register 7 (R7)**
- Register 9: Cortex General-Purpose Register 8 (R8)**
- Register 10: Cortex General-Purpose Register 9 (R9)**
- Register 11: Cortex General-Purpose Register 10 (R10)**
- Register 12: Cortex General-Purpose Register 11 (R11)**
- Register 13: Cortex General-Purpose Register 12 (R12)**

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

Cortex General-Purpose Register 0 (R0)

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R/W	-	Register data.

Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the `ASP` bit in the **Control Register (CONTROL)** register. When the `ASP` bit is clear, this register is the **Main Stack Pointer (MSP)**. When the `ASP` bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the `ASP` bit is clear, and the processor loads the **MSP** with the value from address `0x0000.0000`. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

Stack Pointer (SP)

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SP															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SP															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	SP	R/W	-	This field is the address of the stack pointer.

Register 15: Link Register (LR)

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. **LR** can be accessed from either privileged or unprivileged mode.

`EXC_RETURN` is loaded into **LR** on exception entry. See Table 2-10 on page 104 for the values and description.

Link Register (LR)

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	LINK	R/W	0xFFFF.FFFF	This field is the return address.

Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the **THUMB** bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

Program Counter (PC)

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PC															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PC															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	PC	R/W	-	This field is the current program address.

Register 17: Program Status Register (PSR)

Note: This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27, bits 19:16
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 7:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

APSR contains the current state of the condition flags from previous instruction executions.

EPSR contains the Thumb state bit and the execution state bits for the If-Then (**IT**) instruction or the Interruptible-Continuable Instruction (**ICI**) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the **MSR** instruction always return zero. Attempts to write the **EPSR** using the **MSR** instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 101).

IPSR contains the exception type number of the current Interrupt Service Routine (**ISR**).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the **MSR** or **MRS** instructions. For example, all of the registers can be read using **PSR** with the **MRS** instruction, or **APSR** only can be written to using **APSR** with the **MSR** instruction. page 74 shows the possible register combinations for the **PSR**. See the **MRS** and **MSR** instruction descriptions in the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information about how to access the program status registers.

Table 2-3. PSR Register Combinations

Register	Type	Combination
PSR	R/W ^{a, b}	APSR , EPSR , and IPSR
IEPSR	RO	EPSR and IPSR
IAPSR	R/W ^a	APSR and IPSR
EAPSR	R/W ^b	APSR and EPSR

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

Program Status Register (PSR)

Type R/W, reset 0x0100.0000

See “Exception Types” on page 95 for more information.

The value of this field is only meaningful when accessing **PSR** or **IPSR**.

Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **PRIMASK** register, and the **CPS** instruction may be used to change the value of the **PRIMASK** register. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 95.

Priority Mask Register (PRIMASK)

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	PRIMASK	R/W	0	Priority Mask
				Value Description
				1 Prevents the activation of all exceptions with configurable priority.
				0 No effect.

Register 19: Fault Mask Register (FAULTMASK)

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **FAULTMASK** register, and the **CPS** instruction may be used to change the value of the **FAULTMASK** register. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 95.

Fault Mask Register (FAULTMASK)

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	FAULTMASK	R/W	0	Fault Mask

Value Description

1	Prevents the activation of all exceptions except for NMI.
0	No effect.

The processor clears the **FAULTMASK** bit on exit from any exception handler except the NMI handler.

Register 20: Base Priority Mask Register (BASEPRI)

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 95.

Base Priority Mask Register (BASEPRI)

Type R/W, reset 0x0000.0000

Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode, and indicates whether the FPU state is active. This register is only accessible in privileged mode.

Handler mode always uses **MSP**, so the processor ignores explicit writes to the **ASP** bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the **EXC_RETURN** value (see Table 2-10 on page 104). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses **MSP**. To switch the stack pointer used in Thread mode to **PSP**, either use the **MSR** instruction to set the **ASP** bit, as detailed in the *Cortex™-M3/M4 Instruction Set Technical User's Manual*, or perform an exception return to Thread mode with the appropriate **EXC_RETURN** value, as shown in Table 2-10 on page 104.

Note: When changing the stack pointer, software must use an **ISB** instruction immediately after the **MSR** instruction, ensuring that instructions after the **ISB** execute use the new stack pointer. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

Control Register (CONTROL)

Type R/W, reset 0x0000.0000

2	FPCA	R/W	0	Floating-Point Context Active
				Value Description
				1 Floating-point context active
				0 No floating-point context active
				The Cortex-M4F uses this bit to determine whether to preserve floating-point state when processing an exception.

Important: Two bits control when **FPCA** can be enabled: the **ASPEN** bit in the **Floating-Point Context Control (FPCC)** register and the **DISFPCA** bit in the **Auxiliary Control (ACTLR)** register.

Bit/Field	Name	Type	Reset	Description
1	ASP	R/W	0	Active Stack Pointer Value Description 1 PSP is the current stack pointer. 0 MSP is the current stack pointer In Handler mode, this bit reads as zero and ignores writes. The Cortex-M4F updates this bit automatically on exception return.
0	TMPL	R/W	0	Thread Mode Privilege Level Value Description 1 Unprivileged software can be executed in Thread mode. 0 Only privileged software can be executed in Thread mode.

Register 22: Floating-Point Status Control (FPSC)

The **FPSC** register provides all necessary user-level control of the floating-point system.

Floating-Point Status Control (FPSC)

0	IOC	R/W	-	<p>Invalid Operation Cumulative Exception</p> <p>When set, indicates this exception has occurred since 0 was last written to this bit.</p>

2.3.5 Exceptions and Interrupts

The Cortex-M4F processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 101 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 118 for more information.

2.3.6 Data Types

The Cortex-M4F supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 87 for more information.

2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the LM4F120B2QR controller is provided in Table 2-4 on page 85. In this manual, register addresses are given as a hexadecimal increment, relative to the module’s base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 90).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M4 Peripherals” on page 116).

Note: Within the memory map, all reserved space returns a bus fault when read or written.

2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.
- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 89).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

2.4.3 Behavior of Memory Accesses

Table 2-5 on page 88 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 87 for more information on memory types and the XN attribute. Stellaris devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 85 for more information).

Table 2-5. Memory Access Behavior

Address Range	Memory Region	Memory Type	Execute Never (XN)	Description
0x0000.0000 - 0x1FFF.FFFF	Code	Normal	-	This executable region is for program code. Data can also be stored here.
0x2000.0000 - 0x3FFF.FFFF	SRAM	Normal	-	This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 90).
0x4000.0000 - 0x5FFF.FFFF	Peripheral	Device	XN	This region includes bit band and bit band alias areas (see Table 2-7 on page 90).
0x6000.0000 - 0x9FFF.FFFF	External RAM	Normal	-	This executable region is for data.
0xA000.0000 - 0xDFFF.FFFF	External device	Device	XN	This region is for external device memory.
0xE000.0000 - 0xE00F.FFFF	Private peripheral bus	Strongly Ordered	XN	This region includes the NVIC, system timer, and system control block.
0xE010.0000 - 0xFFFF.FFFF	Reserved	-	-	-

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M4F has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 119.

The Cortex-M4F prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 88 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M4F has the following memory barrier instructions:

- The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (ISB) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming
 - If the MPU settings are changed and the change must be effective on the very next instruction, use a DSB instruction to ensure the effect of the MPU takes place immediately at the end of context switching.
 - Use an ISB instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an ISB instruction is not required.
- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a DMB instruction between the operations. The DMB instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.
- Self-modifying code

If a program contains self-modifying code, use an ISB instruction immediately after the code modification in the program. The ISB instruction ensures subsequent instruction execution uses the updated program.
- Memory map switching

If the system contains a memory map switching mechanism, use a DSB instruction after switching the memory map in the program. The DSB instruction ensures subsequent instruction execution uses the updated memory map.

- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use DSB instructions after the change. The change then takes effect on completion of the DSB instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of DMB instructions.

For more information on the memory barrier instructions, see the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 90. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band region, as shown in Table 2-7 on page 90. For the specific address range of the bit-band regions, see Table 2-4 on page 85.

Note: A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

Table 2-6. SRAM Memory Bit-Banding Regions

Address Range	Memory Region	Instruction and Data Accesses
0x2000.0000 - 0x200F.FFFF	SRAM bit-band region	Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.
0x2200.0000 - 0x23FF.FFFF	SRAM bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped.

Table 2-7. Peripheral Memory Bit-Banding Regions

Address Range	Memory Region	Instruction and Data Accesses
0x4000.0000 - 0x400F.FFFF	Peripheral bit-band region	Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.
0x4200.0000 - 0x43FF.FFFF	Peripheral bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted.

The following formula shows how the alias region maps onto the bit-band region:

$$\text{bit_word_offset} = (\text{byte_offset} \times 32) + (\text{bit_number} \times 4)$$

$$\text{bit_word_addr} = \text{bit_band_base} + \text{bit_word_offset}$$

where:

`bit_word_offset`

The position of the target bit in the bit-band memory region.

`bit_word_addr`

The address of the word in the alias memory region that maps to the targeted bit.

`bit_band_base`

The starting address of the alias region.

`byte_offset`

The number of the byte in the bit-band region that contains the targeted bit.

`bit_number`

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 92 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF*32) + (0*4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF*32) + (7*4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0*32) + (0*4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0*32) + (7*4)$$

Figure 2-4. Bit-Band Mapping

2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

2.4.5.2 Directly Accessing a Bit-Band Region

“Behavior of Memory Accesses” on page 88 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 93 illustrates how data is stored.

Figure 2-5. Data Storage

2.4.7 Synchronization Primitives

The Cortex-M4F instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions `LDREX` and `STREX`
- The halfword instructions `LDREXH` and `STREXH`
- The byte instructions `LDREXB` and `STREXB`

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit.

If the status bit is clear, the read-modify-write completed successfully. If the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4F includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

2.5 Exception Model

The ARM Cortex-M4F processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 96 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 65 interrupts (listed in Table 2-9 on page 97).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRIn)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (ENn)** register and prioritized with the NVIC **Interrupt Priority n (PRIn)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 118.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

Important: After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source de-assert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

See “Nested Vectored Interrupt Controller (NVIC)” on page 118 for more information on exceptions and interrupts.

2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
- **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active.** An exception that is being serviced by the processor but has not completed.
Note: An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.
- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
 - An undefined instruction
 - An illegal unaligned access
 - Invalid state on instruction execution

- An error on exception return

An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.

- **SVC**Call. A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor**. This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV**. PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick**. A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ)**. An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 97 lists the interrupts on the LM4F120B2QR controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 96 shows as having configurable priority (see the **SYSHNDCTRL** register on page 167 and the **DIS0** register on page 138).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 104.

Table 2-8. Exception Types

Exception Type	Vector Number	Priority ^a	Vector Address or Offset ^b	Activation
-	0	-	0x0000.0000	Stack top is loaded from the first entry of the vector table on reset.
Reset	1	-3 (highest)	0x0000.0004	Asynchronous
Non-Maskable Interrupt (NMI)	2	-2	0x0000.0008	Asynchronous
Hard Fault	3	-1	0x0000.000C	-
Memory Management	4	programmable ^c	0x0000.0010	Synchronous
Bus Fault	5	programmable ^c	0x0000.0014	Synchronous when precise and asynchronous when imprecise
Usage Fault	6	programmable ^c	0x0000.0018	Synchronous
-	7-10	-	-	Reserved
SVCCall	11	programmable ^c	0x0000.002C	Synchronous
Debug Monitor	12	programmable ^c	0x0000.0030	Synchronous
-	13	-	-	Reserved

Table 2-8. Exception Types (continued)

Exception Type	Vector Number	Priority ^a	Vector Address or Offset ^b	Activation
PendSV	14	programmable ^c	0x0000.0038	Asynchronous
SysTick	15	programmable ^c	0x0000.003C	Asynchronous
Interrupts	16 and above	programmable ^d	0x0000.0040 and above	Asynchronous

a. 0 is the default priority for all the programmable priorities.

b. See "Vector Table" on page 99.

c. See **SYSPRI1** on page 164.

d. See **PRIn** registers on page 146.

Table 2-9. Interrupts

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Vector Address or Offset	Description
0-15	-	0x0000.0000 - 0x0000.003C	Processor exceptions

110	94	0x0000.01B8	32/64-Bit Timer 0A
111	95	0x0000.01BC	32/64-Bit Timer 0B
112	96	0x0000.01C0	32/64-Bit Timer 1A
113	97	0x0000.01C4	32/64-Bit Timer 1B
114	98	0x0000.01C8	32/64-Bit Timer 2A
115	99	0x0000.01CC	32/64-Bit Timer 2B
116	100	0x0000.01D0	32/64-Bit Timer 3A
117	101	0x0000.01D4	32/64-Bit Timer 3B

Table 2-9. Interrupts (continued)

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Vector Address or Offset	Description
118	102	0x0000.01D8	32/64-Bit Timer 4A
119	103	0x0000.01DC	32/64-Bit Timer 4B
120	104	0x0000.01E0	32/64-Bit Timer 5A
121	105	0x0000.01E4	32/64-Bit Timer 5B
122	106	0x0000.01E8	System Exception (imprecise)
123-147	107-131	-	Reserved

2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCcall, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 96. Figure 2-6 on page 100 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

Figure 2-6. Vector Table

Exception number	IRQ number	Offset	Vector
147	131	0x0254	IRQ131
.	.	.	.
.	.	.	.
18	2	0x004C	IRQ2
17	1	0x0048	IRQ1
16	0	0x0044	IRQ0
15	-1	0x0040	Systick
14	-2	0x003C	PendSV
13		0x0038	Reserved
12			Reserved for Debug
11	-5	0x002C	SVCcall
10			Reserved
9			
8			
7			
6	-10	0x0018	Usage fault
5	-11	0x0014	Bus fault
4	-12	0x0010	Memory management fault
3	-13	0x000C	Hard fault
2	-14	0x0008	NMI
1		0x0004	Reset
		0x0000	Initial SP value

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0400 to 0x3FFF.FC00 (see “Vector Table” on page 99). Note that when configuring the **VTABLE** register, the offset must be aligned on a 1024-byte boundary.

2.5.5 Exception Priorities

As Table 2-8 on page 96 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 164 and page 146.

Note: Configurable priority values for the Stellaris implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 158.

2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 101 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 102 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 103 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On

return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 78, **FAULTMASK** on page 79, and **BASEPRI** on page 80). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

When using floating-point routines, the Cortex-M4F processor automatically stacks the architected floating-point state on exception entry. Figure 2-7 on page 103 shows the Cortex-M4F stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

Note: Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. Figure 2-7 on page 103 shows this stack frame also.

Figure 2-7. Exception Stack Frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel to the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an **EXC_RETURN** value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the **EXC_RETURN** value into the **PC**:

- An `LDM` or `POP` instruction that loads the **PC**
- A `BX` instruction using any register
- An `LDR` instruction with the **PC** as the destination

`EXC_RETURN` is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. Table 2-10 on page 104 shows the `EXC_RETURN` values with a description of the exception return behavior.

`EXC_RETURN` bits 31:5 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

Table 2-10. Exception Return Behavior

<code>EXC_RETURN[31:0]</code>	Description
0xFFFF.FFE0	Reserved
0xFFFF.FFE1	Return to Handler mode. Exception return uses floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFE2 - 0xFFFF.FFE8	Reserved
0xFFFF.FFE9	Return to Thread mode. Exception return uses floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFEA - 0xFFFF.FFEC	Reserved
0xFFFF.FFED	Return to Thread mode. Exception return uses floating-point state from PSP . Execution uses PSP after return.
0xFFFF.FFEE - 0xFFFF.FFF0	Reserved
0xFFFF.FFF1	Return to Handler mode. Exception return uses non-floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFF2 - 0xFFFF.FFF8	Reserved
0xFFFF.FFF9	Return to Thread mode. Exception return uses non-floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFFA - 0xFFFF.FFFC	Reserved
0xFFFF.FFFD	Return to Thread mode. Exception return uses non-floating-point state from PSP . Execution uses PSP after return.
0xFFFF.FFFE - 0xFFFF.FFFF	Reserved

2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 94). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.

- An internally detected error such as an undefined instruction or an attempt to change state with a BX instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

2.6.1 Fault Types

Table 2-11 on page 105 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 171 for more information about the fault status registers.

Table 2-11. Faults

Fault	Handler	Fault Status Register	Bit Name
Bus error on a vector read	Hard fault	Hard Fault Status (HFAULTSTAT)	VECT
Fault escalated to a hard fault	Hard fault	Hard Fault Status (HFAULTSTAT)	FORCED
MPU or default memory mismatch on instruction access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	IERR ^a
MPU or default memory mismatch on data access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	DERR
MPU or default memory mismatch on exception stacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MSTKE
MPU or default memory mismatch on exception unstacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MUSTKE
MPU or default memory mismatch during lazy floating-point state preservation	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MLSPERR
Bus error during exception stacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BSTKE
Bus error during exception unstacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BUSTKE
Bus error during instruction prefetch	Bus fault	Bus Fault Status (BFAULTSTAT)	IBUS
Bus error during lazy floating-point state preservation	Bus fault	Bus Fault Status (BFAULTSTAT)	BLSPE
Precise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	PRECISE
Imprecise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	IMPRE
Attempt to access a coprocessor	Usage fault	Usage Fault Status (UFAULTSTAT)	NOCP
Undefined instruction	Usage fault	Usage Fault Status (UFAULTSTAT)	UNDEF
Attempt to enter an invalid instruction set state ^b	Usage fault	Usage Fault Status (UFAULTSTAT)	INVSTAT
Invalid EXC_RETURN value	Usage fault	Usage Fault Status (UFAULTSTAT)	INVPC
Illegal unaligned load or store	Usage fault	Usage Fault Status (UFAULTSTAT)	UNALIGN
Divide by 0	Usage fault	Usage Fault Status (UFAULTSTAT)	DIV0

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiple instruction with ICI continuation.

2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 164). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 167).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 94.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

Note: Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 106.

Table 2-12. Fault Status and Fault Address Registers

Handler	Status Register Name	Address Register Name	Register Description
Hard fault	Hard Fault Status (HFAULTSTAT)	-	page 177
Memory management fault	Memory Management Fault Status (MFAULTSTAT)	Memory Management Fault Address (MMADDR)	page 171 page 178
Bus fault	Bus Fault Status (BFAULTSTAT)	Bus Fault Address (FAULTADDR)	page 171 page 179
Usage fault	Usage Fault Status (UFAULTSTAT)	-	page 171

2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset, an NMI occurs, or it is halted by a debugger.

Note: If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

2.7 Power Management

The Cortex-M4F processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The `SLEEPDEEP` bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 160). For more information about the behavior of the sleep modes, see “System Control” on page 220.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, `WFI`, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 108). When the processor executes a `WFI` instruction, it stops executing instructions and enters sleep mode. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information.

2.7.1.2 Wait for Event

The wait for event instruction, `WFE`, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a `WFE` instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a `WFE` instruction. Typically, this situation occurs if an `SEV` instruction has been executed. Software cannot access this register directly.

See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information.

2.7.1.3 Sleep-on-Exit

If the `SLEEPEXIT` bit of the **SYSCTRL** register is set, when the processor completes the execution of all exception handlers, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that cause it to enter sleep mode.

2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when the NVIC detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the `PRIMASK` bit and clearing the `FAULTMASK` bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears `PRIMASK`. For more information about **PRIMASK** and **FAULTMASK**, see page 78 and page 79.

2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the `SEVONPEND` bit in the **SYSCTRL** register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about **SYSCTRL**, see page 160.

2.7.3 The Wake-Up Interrupt Controller

The Wake-Up Interrupt Controller (WIC) is a peripheral that can detect an interrupt and wake the processor from deep sleep mode. The WIC is enabled only when the `DEEPSLEEP` bit in the **SCR** register is set (see page 160).

The WIC is not programmable, and does not have any registers or user interface. It operates entirely from hardware signals.

When the WIC is enabled and the processor enters deep sleep mode, the power management unit in the system can power down most of the Cortex-M4F processor. This has the side effect of stopping the SysTick timer. When the WIC receives an interrupt, it takes a number of clock cycles to wake up the processor and restore its state, before it can process the interrupt. This means interrupt latency is increased in deep sleep mode.

Note: If the processor detects a connection to a debugger it disables the WIC.

2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 108 lists the supported instructions.

Note: In Table 2-13 on page 108:

- Angle brackets, `<>`, enclose alternative forms of the operand
- Braces, `{}`, enclose optional operands
- The Operands column is not exhaustive
- `Op2` is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *ARM® Cortex™-M4 Technical Reference Manual*.

Table 2-13. Cortex-M4F Instruction Summary

Mnemonic	Operands	Brief Description	Flags
ADC, ADCS	{Rd,} Rn, Op2	Add with carry	N, Z, C, V
ADD, ADDS	{Rd,} Rn, Op2	Add	N, Z, C, V
ADD, ADDW	{Rd,} Rn, #imm12	Add	-

Table 2-13. Cortex-M4F Instruction Summary (continued)

Mnemonic	Operands	Brief Description	Flags
ADR	Rd, label	Load PC-relative address	-
AND, ANDS	{Rd,} Rn, Op2	Logical AND	N, Z, C
ASR, ASRS	Rd, Rm, <Rs #n>	Arithmetic shift right	N, Z, C
B	label	Branch	-
BFC	Rd, #lsb, #width	Bit field clear	-
BFI	Rd, Rn, #lsb, #width	Bit field insert	-
BIC, BICS	{Rd,} Rn, Op2	Bit clear	N, Z, C
BKPT	#imm	Breakpoint	-
BL	label	Branch with link	-
BLX	Rm	Branch indirect with link	-
BX	Rm	Branch indirect	-
CBNZ	Rn, label	Compare and branch if non-zero	-
CBZ	Rn, label	Compare and branch if zero	-
CLREX	-	Clear exclusive	-
CLZ	Rd, Rm	Count leading zeros	-
CMN	Rn, Op2	Compare negative	N, Z, C, V
CMP	Rn, Op2	Compare	N, Z, C, V
CPSID	i	Change processor state, disable interrupts	-
CPSIE	i	Change processor state, enable interrupts	-
DMB	-	Data memory barrier	-
DSB	-	Data synchronization barrier	-
EOR, EORS	{Rd,} Rn, Op2	Exclusive OR	N, Z, C
ISB	-	Instruction synchronization barrier	-
IT	-	If-Then condition block	-

3 Cortex-M4 Peripherals

This chapter provides information on the Stellaris[®] implementation of the Cortex-M4 processor peripherals, including:

- **SysTick** (see page 117)
 - Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.
- **Nested Vectored Interrupt Controller (NVIC)** (see page 118)
 - Facilitates low-latency exception and interrupt handling
 - Controls power management
 - Implements system control registers
- **System Control Block (SCB)** (see page 119)
 - Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.
- **Memory Protection Unit (MPU)** (see page 119)
 - Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.
- **Floating-Point Unit (FPU)** (see page 124)
 - Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

Table 3-1 on page 116 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

Table 3-1. Core Peripheral Register Regions

Address	Core Peripheral	Description (see page ...)
0xE000.E010-0xE000.E01F	System Timer	117
0xE000.E100-0xE000.E4EF 0xE000.EF00-0xE000.EF03	Nested Vectored Interrupt Controller	118
0xE000.E008-0xE000.E00F 0xE000.ED00-0xE000.ED3F	System Control Block	119
0xE000.ED90-0xE000.EDB8	Memory Protection Unit	119
0xE000.EF30-0xE000.EF44	Floating Point Unit	124

3.1 Functional Description

This chapter provides information on the Stellaris implementation of the Cortex-M4 processor peripherals: SysTick, NVIC, SCB and MPU.

3.1.1 System Timer (SysTick)

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The `COUNT` bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the `COUNT` status bit is set. The `COUNT` bit clears on reads.

Writing to the **STCURRENT** register clears the register and the `COUNT` status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on either the system clock or the precision internal oscillator (PIOSC) divided by 4. If this clock signal is stopped for low power mode, the SysTick counter stops. SysTick can be kept running during Deep-sleep mode by setting the `CLK_SRC` bit in the **SysTick Control and Status Register (STCTRL)** register and ensuring that the `PIOSCPD` bit in the **Deep Sleep Clock Configuration (DSLPCCLKCFG)** register is clear. Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset; the correct initialization sequence for the SysTick counter is:

1. Program the value in the **STRELOAD** register.
2. Clear the **STCURRENT** register by writing to it with any value.
3. Configure the **STCTRL** register for the required operation.

Note: When the processor is halted for debugging, the counter does not decrement.

3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 65 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 118 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the `INT` bit in the **PEND0** register on page 140 or **SWTRIG** on page 150.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
 - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
 - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
 - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
 - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 87 for more information).

Table 3-2 on page 120 shows the possible MPU region attributes. See the section called “MPU Configuration for a Stellaris Microcontroller” on page 124 for guidelines for programming a microcontroller implementation.

Table 3-2. Memory Attributes Summary

Memory Type	Description
Strongly Ordered	All accesses to Strongly Ordered memory occur in program order.
Device	Memory-mapped peripherals
Normal	Normal memory

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASEx** and **MPUATTRx** aliases to program up to four regions simultaneously using an *STM* instruction.

Updating an MPU Region Using Separate Words

This example simple code configures one region:

```

; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]     ; Region Number
STR R4, [R0, #0x4]     ; Region Base Address
STRH R2, [R0, #0x8]    ; Region Size and Enable
STRH R3, [R0, #0xA]    ; Region Attribute

```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```

; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register

```

```

STR R1, [R0, #0x0]           ; Region Number
BIC R2, R2, #1               ; Disable
STRH R2, [R0, #0x8]         ; Region Size and Enable
STR R4, [R0, #0x4]          ; Region Base Address
STRH R3, [R0, #0xA]         ; Region Attribute
ORR R2, #1                   ; Enable
STRH R2, [R0, #0x8]         ; Region Size and Enable

```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a DSB instruction and an ISB instruction should be used. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an ISB is not required.

Updating an MPU Region Using Multi-Word Writes

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable

```

An STM instruction can be used to optimize this:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3} ; Region number, address, attribute, size and enable

```

This operation can be done in two words for pre-packed information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 184) contains the required region number and has the VALID bit set. This method can be used when the data is statically packed, for example in a boot loader:

```

; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE      ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]    ; Region base address and region number combined
                        ; with VALID (bit 4) set
STR R2, [R0, #0x4]    ; Region Attribute, Size and Enable

```

Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the `SRD` field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 186) to disable a subregion. The least-significant bit of the `SRD` field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the `SRD` field must be configured to `0x00`, otherwise the MPU behavior is unpredictable.

Example of SRD Use

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the `SRD` field for region two to `0x03` to disable the first two subregions, as Figure 3-1 on page 122 shows.

Figure 3-1. SRD Use Example

3.1.4.2 MPU Access Permission Attributes

The access permission bits, `TEX`, `S`, `C`, `B`, `AP`, and `XN` of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 122 shows the encodings for the `TEX`, `C`, `B`, and `S` access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M4 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Stellaris Microcontroller” on page 124 for information on programming the MPU for Stellaris implementations.

Table 3-3. TEX, S, C, and B Bit Field Encoding

TEX	S	C	B	Memory Type	Shareability	Other Attributes
000b	x ^a	0	0	Strongly Ordered	Shareable	-
000	x ^a	0	1	Device	Shareable	-

Table 3-3. TEX, S, C, and B Bit Field Encoding (continued)

TEX	S	C	B	Memory Type	Shareability	Other Attributes
000	0	1	0	Normal	Not shareable	Outer and inner write-through. No write allocate.
000	1	1	0	Normal	Shareable	
000	0	1	1	Normal	Not shareable	
000	1	1	1	Normal	Shareable	
001	0	0	0	Normal	Not shareable	Outer and inner noncacheable.
001	1	0	0	Normal	Shareable	
001	x ^a	0	1	Reserved encoding	-	-
001	x ^a	1	0	Reserved encoding	-	-
001	0	1	1	Normal	Not shareable	Outer and inner write-back. Write and read allocate.
001	1	1	1	Normal	Shareable	
010	x ^a	0	0	Device	Not shareable	Nonshared Device.
010	x ^a	0	1	Reserved encoding	-	-
010	x ^a	1	x ^a	Reserved encoding	-	-
1BB	0	A	A	Normal	Not shareable	Cached memory (BB = outer policy, AA = inner policy). See Table 3-4 for the encoding of the AA and BB bits.
1BB	1	A	A	Normal	Shareable	

a. The MPU ignores the value of this bit.

Table 3-4 on page 123 shows the cache policy for memory attribute encodings with a TEX value in the range of 0x4-0x7.

Table 3-4. Cache Policy for Memory Attribute Encoding

Encoding, AA or BB	Corresponding Cache Policy
00	Non-cacheable
01	Write back, write and read allocate
10	Write through, no write allocate
11	Write back, no write allocate

Table 3-5 on page 123 shows the AP encodings in the MPUATTR register that define the access permissions for privileged and unprivileged software.

Table 3-5. AP Bit Field Encoding

AP Bit Field	Privileged Permissions	Unprivileged Permissions	Description
000	No access	No access	All accesses generate a permission fault.
001	R/W	No access	Access from privileged software only.
010	R/W	RO	Writes by unprivileged software generate a permission fault.
011	R/W	R/W	Full access.
100	Unpredictable	Unpredictable	Reserved.
101	RO	No access	Reads by privileged software only.

Table 3-5. AP Bit Field Encoding (continued)

AP Bit Field	Privileged Permissions	Unprivileged Permissions	Description
110	RO	RO	Read-only, by privileged or unprivileged software.
111	RO	RO	Read-only, by privileged or unprivileged software.

MPU Configuration for a Stellaris Microcontroller

Stellaris microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 124.

Table 3-6. Memory Region Attributes for Stellaris Microcontrollers

Memory Region	TEX	S	C	B	Memory Type and Attributes
Flash memory	000b	0	1	0	Normal memory, non-shareable, write-through
Internal SRAM	000b	1	1	0	Normal memory, shareable, write-through
External SRAM	000b	1	1	1	Normal memory, shareable, write-back, write-allocate
Peripherals	000b	1	0	1	Device memory, shareable

In current Stellaris microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

3.1.4.3 MPU Mismatch

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 85 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 171 for more information.

3.1.5 Floating-Point Unit (FPU)

This section describes the Floating-Point Unit (FPU) and the registers it uses. The FPU provides:

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined Multiply and Accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

The Cortex-M4F FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU's single-precision extension registers can also be accessed as 16 doubleword registers for load, store, and move operations.

3.1.5.1 FPU Views of the Register Bank

The FPU provides an extension register file containing 32 single-precision registers. These can be viewed as:

- Sixteen 64-bit doubleword registers, D0-D15
- Thirty-two 32-bit single-word registers, S0-S31
- A combination of registers from the above views

Figure 3-2. FPU Register Bank

The mapping between the registers is as follows:

- $S_{\langle 2n \rangle}$ maps to the least significant half of $D_{\langle n \rangle}$
- $S_{\langle 2n+1 \rangle}$ maps to the most significant half of $D_{\langle n \rangle}$

For example, you can access the least significant half of the value in D6 by accessing S12, and the most significant half of the elements by accessing S13.

3.1.5.2 Modes of Operation

The FPU provides three modes of operation to accommodate a variety of applications.

Full-Compliance mode. In Full-Compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

Flush-to-Zero mode. Setting the **FZ** bit of the **Floating-Point Status and Control (FPSC)** register enables Flush-to-Zero mode. In this mode, the FPU treats all subnormal input operands of arithmetic CDP operations as zeros in the operation. Exceptions that result from a zero operand are signalled appropriately. VABS, VNEG, and VMOV are not considered arithmetic CDP operations and are not affected by Flush-to-Zero mode. A result that is tiny, as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding, is replaced with a zero. The **IDC** bit in **FPSC** indicates when an input flush occurs. The **UFC** bit in **FPSC** indicates when a result flush occurs.

Default NaN mode. Setting the **DN** bit in the **FPSC** register enables default NaN mode. In this mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. Propagation of the fraction bits is maintained only by VABS,

VNEG, and VMOV operations. All other CDP operations ignore any information in the fraction bits of an input NaN.

3.1.5.3 Compliance with the IEEE 754 standard

When Default NaN (DN) and Flush-to-Zero (FZ) modes are disabled, FPv4 functionality is compliant with the IEEE 754 standard in hardware. No support code is required to achieve this compliance.

3.1.5.4 Complete Implementation of the IEEE 754 standard

The Cortex-M4F floating point instruction set does not support all operations defined in the IEEE 754-2008 standard. Unsupported operations include, but are not limited to the following:

- Remainder
- Round floating-point number to integer-valued floating-point number
- Binary-to-decimal conversions
- Decimal-to-binary conversions
- Direct comparison of single-precision and double-precision values

The Cortex-M4 FPU supports fused MAC operations as described in the IEEE standard. For complete implementation of the IEEE 754-2008 standard, floating-point functionality must be augmented with library functions.

3.1.5.5 IEEE 754 standard implementation choices

NaN handling

All single-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most-significant fraction bit of zero indicates a Signaling NaN (SNaN). A one indicates a Quiet NaN (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. The below table shows the default NaN values.

Sign	Fraction	Fraction
0	0xFF	bit [22] = 1, bits [21:0] are all zeros

Processing of input NaNs for ARM floating-point functionality and libraries is defined as follows:

- In full-compliance mode, NaNs are handled as described in the ARM Architecture Reference Manual. The hardware processes the NaNs directly for arithmetic CDP instructions. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception. For the non-arithmetic CDP instructions, VABS, VNEG, and VMOV, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception.
- In default NaN mode, arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and non-arithmetic CDP instructions is the same as in full-compliance mode.

Table 3-7. QNaN and SNaN Handling

Instruction Type	Default NaN Mode	With QNaN Operand	With SNaN Operand
Arithmetic CDP	Off	The QNaN or one of the QNaN operands, if there is more than one, is returned according to the rules given in the ARM Architecture Reference Manual.	IOC ^a set. The SNaN is quieted and the result NaN is determined by the rules given in the ARM Architecture Reference Manual.
	On	Default NaN returns.	IOCa set. Default NaN returns.
Non-arithmetic CDP	Off/On	NaN passes to destination with sign changed as appropriate.	
FCMP(Z)	-	Unordered compare.	IOC set. Unordered compare.
FCMPE(Z)	-	IOC set. Unordered compare.	IOC set. Unordered compare.
Load/store	Off/On	All NaNs transferred.	

a. IOC is the Invalid Operation exception flag, FPSCR[0].

Comparisons

Comparison results modify the flags in the FPSCR. You can use the MVRS APSR_nzcv instruction (formerly FMSTAT) to transfer the current flags from the FPSCR to the APSR. See the ARM Architecture Reference Manual for mapping of IEEE 754-2008 standard predicates to ARM conditions. The flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE standard.

Underflow

The Cortex-M4F FPU uses the before rounding form of tininess and the inexact result form of loss of accuracy as described in the IEEE 754-2008 standard to generate Underflow exceptions.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE standard, are flushed to a zero, and the UFC flag, FPSCR[3], is set. See the ARM Architecture Reference Manual for information on flush-to-zero mode.

When the FPU is not in flush-to-zero mode, operations are performed on subnormal operands. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set if the result was also inexact.

3.1.5.6 Exceptions

The FPU sets the cumulative exception status flag in the FPSCR register as required for each instruction, in accordance with the FPv4 architecture. The FPU does not support user-mode traps. The exception enable bits in the FPSCR read-as-zero, and writes are ignored. The processor also has six output pins, FPIXC, FPUFC, FPOFC, FPDZC, FPIDC, and FPIOC, that each reflect the status of one of the cumulative exception flags. See the Cortex-M4 Integration and Implementation Manual for a description of these outputs.

The processor can reduce the exception latency by using lazy stacking. See Auxiliary Control Register, ACTLR on page 4-5. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack. See the ARMv7-M Architecture Reference Manual for more information.

3.1.5.7 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The processor must be in privileged mode to read from and write to the **Coprocessor Access**

Control (CPAC) register. The below example code sequence enables the FPU in both privileged and user modes.

```
; CPACR is located at address 0xE000ED88
LDR.W R0, =0xE000ED88
; Read CPACR
LDR R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors

3.2 Register Map

Table 3-8 on page 128 lists the Cortex-M4 Peripheral SysTick, NVIC, MPU, FPU and SCB registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

Note: Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Table 3-8. Peripherals Register Map

Offset	Name	Type	Reset	Description	See page
System Timer (SysTick) Registers					
0x010	STCTRL	R/W	0x0000.0004	SysTick Control and Status Register	132
0x014	STRELOAD	R/W	-	SysTick Reload Value Register	134

3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

Register 1: SysTick Control and Status Register (STCTRL), offset 0x010

Note: This register can only be accessed from privileged mode.

The SysTick **STCTRL** register enables the SysTick features.

SysTick Control and Status Register (STCTRL)

Base 0xE000.E000

Offset 0x010

Type R/W, reset 0x0000.0004

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description						
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
16	COUNT	RO	0	Count Flag <table border="0" style="margin-left: 20px;"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>The SysTick timer has not counted to 0 since the last time this bit was read.</td> </tr> <tr> <td>1</td> <td>The SysTick timer has counted to 0 since the last time this bit was read.</td> </tr> </table> <p>This bit is cleared by a read of the register or if the STCURRENT register is written with any value.</p> <p>If read by the debugger using the DAP, this bit is cleared only if the MasterType bit in the AHB-AP Control Register is clear. Otherwise, the COUNT bit is not changed by the debugger read. See the <i>ARM® Debug Interface V5 Architecture Specification</i> for more information on MasterType.</p>	Value	Description	0	The SysTick timer has not counted to 0 since the last time this bit was read.	1	The SysTick timer has counted to 0 since the last time this bit was read.
Value	Description									
0	The SysTick timer has not counted to 0 since the last time this bit was read.									
1	The SysTick timer has counted to 0 since the last time this bit was read.									
15:3	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2	CLK_SRC	R/W	1	Clock Source <table border="0" style="margin-left: 20px;"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>Precision internal oscillator (PIOSC) divided by 4</td> </tr> <tr> <td>1</td> <td>System clock</td> </tr> </table>	Value	Description	0	Precision internal oscillator (PIOSC) divided by 4	1	System clock
Value	Description									
0	Precision internal oscillator (PIOSC) divided by 4									
1	System clock									

Bit/Field	Name	Type	Reset	Description
1	INTEN	R/W	0	Interrupt Enable Value Description 0 Interrupt generation is disabled. Software can use the <code>COUNT</code> bit to determine if the counter has ever reached 0. 1 An interrupt is generated to the NVIC when SysTick counts to 0.
0	ENABLE	R/W	0	Enable Value Description 0 The counter is disabled. 1 Enables SysTick to operate in a multi-shot way. That is, the counter loads the <code>RELOAD</code> value and begins counting down. On reaching 0, the <code>COUNT</code> bit is set and an interrupt is generated if enabled by <code>INTEN</code> . The counter then loads the <code>RELOAD</code> value again and begins counting.

Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014

Note: This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the **COUNT** bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the **RELOAD** field.

Note that in order to access this register correctly, the system clock must be faster than 8 MHz.

SysTick Reload Value Register (STRELOAD)

Base 0xE000.E000

Offset 0x014

Type R/W, reset -

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	R/WC	0x00.0000	Current Value This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care. This register is write-clear. Writing to it with any value clears the register. Clearing this register also clears the COUNT bit of the STCTRL register.

3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 157.

Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100**Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104****Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108****Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C**

Note: This register can only be accessed from privileged mode.

The **ENn** registers enable interrupts and show which interrupts are enabled. Bit 0 of **EN0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **EN1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **EN2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **EN3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **EN4** (see page 137) corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131.

See Table 2-9 on page 97 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

Interrupt 0-31 Set Enable (EN0)

Base 0xE000.E000

Offset 0x100

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Enable

Value	Description
0	On a read, indicates the interrupt is disabled. On a write, no effect.
1	On a read, indicates the interrupt is enabled. On a write, enables the interrupt.

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **DISn** register.

Register 8: Interrupt 128-131 Set Enable (EN4), offset 0x110

Note: This register can only be accessed from privileged mode.

The **EN4** register enables interrupts and shows which interrupts are enabled. Bit 0 corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131. See Table 2-9 on page 97 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

Interrupt 128-131 Set Enable (EN4)

Base 0xE000.E000

Offset 0x110

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	INT	R/W	0x0	Interrupt Enable
	Value	Description		
	0	On a read, indicates the interrupt is disabled. On a write, no effect.		
	1	On a read, indicates the interrupt is enabled. On a write, enables the interrupt.		

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **DIS4** register.

Register 9: Interrupt 0-31 Clear Enable (DIS0), offset 0x180**Register 10: Interrupt 32-63 Clear Enable (DIS1), offset 0x184****Register 11: Interrupt 64-95 Clear Enable (DIS2), offset 0x188****Register 12: Interrupt 96-127 Clear Enable (DIS3), offset 0x18C**

Note: This register can only be accessed from privileged mode.

The **DIS_n** registers disable interrupts. Bit 0 of **DIS0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **DIS1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **DIS2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **DIS3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **DIS4** (see page 139) corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131.

See Table 2-9 on page 97 for interrupt assignments.

Interrupt 0-31 Clear Enable (DIS0)

Base 0xE000.E000
Offset 0x180
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Disable

Value Description

0 On a read, indicates the interrupt is disabled.

On a write, no effect.

1 On a read, indicates the interrupt is enabled.

On a write, clears the corresponding **INT**[n] bit in the **EN0** register, disabling interrupt [n].

Register 13: Interrupt 128-131 Clear Enable (DIS4), offset 0x190

Note: This register can only be accessed from privileged mode.

The **DIS4** register disables interrupts. Bit 0 corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131. See Table 2-9 on page 97 for interrupt assignments.

Interrupt 128-131 Clear Enable (DIS4)

Base 0xE000.E000

Offset 0x190

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3:0	INT	R/W	0x0	Interrupt Disable
-----	-----	-----	-----	-------------------

Value Description

0	On a read, indicates the interrupt is disabled.
---	---

	On a write, no effect.
--	------------------------

1	On a read, indicates the interrupt is enabled.
---	--

	On a write, clears the corresponding <code>INT[n]</code> bit in the EN4 register, disabling interrupt [n].
--	---

Register 14: Interrupt 0-31 Set Pending (PEND0), offset 0x200

Register 15: Interrupt 32-63 Set Pending (PEND1), offset 0x204

Register 16: Interrupt 64-95 Set Pending (PEND2), offset 0x208

Register 17: Interrupt 96-127 Set Pending (PEND3), offset 0x20C

Note: This register can only be accessed from privileged mode.

The **DISn** registers force interrupts into the pending state and show which interrupts are pending. Bit 0 of **PEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **PEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **PEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **PEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **PEND4** (see page 141) corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131.

See Table 2-9 on page 97 for interrupt assignments.

Interrupt 0-31 Set Pending (PEND0)

Base 0xE000.E000

Offset 0x200

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Set Pending
	Value		Description	
	0		On a read, indicates that the interrupt is not pending. On a write, no effect.	
	1		On a read, indicates that the interrupt is pending. On a write, the corresponding interrupt is set to pending even if it is disabled.	
	If the corresponding interrupt is already pending, setting a bit has no effect.			
	A bit can only be cleared by setting the corresponding <code>INT[n]</code> bit in the UNPEND0 register.			

Register 18: Interrupt 128-131 Set Pending (PEND4), offset 0x210

Note: This register can only be accessed from privileged mode.

The **PEND4** register forces interrupts into the pending state and shows which interrupts are pending. Bit 0 corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131. See Table 2-9 on page 97 for interrupt assignments.

Interrupt 128-131 Set Pending (PEND4)

Base 0xE000.E000

Offset 0x210

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3:0	INT	R/W	0x0	Interrupt Set Pending
-----	-----	-----	-----	-----------------------

Value	Description
0	On a read, indicates that the interrupt is not pending. On a write, no effect.
1	On a read, indicates that the interrupt is pending. On a write, the corresponding interrupt is set to pending even if it is disabled.

If the corresponding interrupt is already pending, setting a bit has no effect.

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **UNPEND4** register.

Register 19: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280

Register 20: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284

Register 21: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288

Register 22: Interrupt 96-127 Clear Pending (UNPEND3), offset 0x28C

Note: This register can only be accessed from privileged mode.

The **UNPEND_n** registers show which interrupts are pending and remove the pending state from interrupts. Bit 0 of **UNPEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **UNPEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **UNPEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **UNPEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **UNPEND4** (see page 143) corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131.

See Table 2-9 on page 97 for interrupt assignments.

Interrupt 0-31 Clear Pending (UNPEND0)

Base 0xE000.E000
Offset 0x280
Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Clear Pending

Value Description

0 On a read, indicates that the interrupt is not pending.
On a write, no effect.

1 On a read, indicates that the interrupt is pending.
On a write, clears the corresponding **INT[n]** bit in the **PEND0** register, so that interrupt [n] is no longer pending.
Setting a bit does not affect the active state of the corresponding interrupt.

Register 23: Interrupt 128-131 Clear Pending (UNPEND4), offset 0x290

Note: This register can only be accessed from privileged mode.

The **UNPEND4** register shows which interrupts are pending and removes the pending state from interrupts. Bit 0 corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131. See Table 2-9 on page 97 for interrupt assignments.

Interrupt 128-131 Clear Pending (UNPEND4)

Base 0xE000.E000

Offset 0x290

Type R/W, reset 0x0000.0000

Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	INT	R/W	0x0	Interrupt Clear Pending

Value Description

0 On a read, indicates that the interrupt is not pending.
On a write, no effect.

1 On a read, indicates that the interrupt is pending.
On a write, clears the corresponding `INT[n]` bit in the **PEND4** register, so that interrupt [n] is no longer pending.
Setting a bit does not affect the active state of the corresponding interrupt.

Register 24: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300

Register 25: Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304

Register 26: Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308

Register 27: Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C

Note: This register can only be accessed from privileged mode.

The **UNPENDn** registers indicate which interrupts are active. Bit 0 of **ACTIVE0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **ACTIVE1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **ACTIVE2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **ACTIVE3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **ACTIVE4** (see page 145) corresponds to Interrupt 128; bit 3 corresponds to Interrupt 131.

See Table 2-9 on page 97 for interrupt assignments.

Caution – Do not manually set or clear the bits in this register.

Interrupt 0-31 Active Bit (ACTIVE0)

Base 0xE000.E000

Offset 0x300

Type RO, reset 0x0000.0000

3:0	INT	RO	0x0	Interrupt Active
				Value Description
				0 The corresponding interrupt is not active.
				1 The corresponding interrupt is active, or active and pending.

- Register 29: Interrupt 0-3 Priority (PRI0), offset 0x400**
Register 30: Interrupt 4-7 Priority (PRI1), offset 0x404
Register 31: Interrupt 8-11 Priority (PRI2), offset 0x408
Register 32: Interrupt 12-15 Priority (PRI3), offset 0x40C
Register 33: Interrupt 16-19 Priority (PRI4), offset 0x410
Register 34: Interrupt 20-23 Priority (PRI5), offset 0x414
Register 35: Interrupt 24-27 Priority (PRI6), offset 0x418
Register 36: Interrupt 28-31 Priority (PRI7), offset 0x41C
Register 37: Interrupt 32-35 Priority (PRI8), offset 0x420
Register 38: Interrupt 36-39 Priority (PRI9), offset 0x424
Register 39: Interrupt 40-43 Priority (PRI10), offset 0x428
Register 40: Interrupt 44-47 Priority (PRI11), offset 0x42C
Register 41: Interrupt 48-51 Priority (PRI12), offset 0x430
Register 42: Interrupt 52-55 Priority (PRI13), offset 0x434
Register 43: Interrupt 56-59 Priority (PRI14), offset 0x438
Register 44: Interrupt 60-63 Priority (PRI15), offset 0x43C

Note: This register can only be accessed from privileged mode.

The **PRI_n** registers (see also page 148) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

PRI_n Register Bit Field	Interrupt
Bits 31:29	Interrupt [4n+3]
Bits 23:21	Interrupt [4n+2]
Bits 15:13	Interrupt [4n+1]
Bits 7:5	Interrupt [4n]

See Table 2-9 on page 97 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRI_{GROUP}** field in the **Application Interrupt and Reset Control (APINT)** register (see page 158) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

Interrupt 0-3 Priority (PRIO)

Base 0xE000.E000

Offset 0x400

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:29	INTD	R/W	0x0	Interrupt Priority for Interrupt [4n+3] This field holds a priority value, 0-7, for the interrupt with the number [4n+3], where n is the number of the Interrupt Priority register (n=0 for PRIO , and so on). The lower the value, the greater the priority of the corresponding interrupt.
28:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:21	INTC	R/W	0x0	Interrupt Priority for Interrupt [4n+2] This field holds a priority value, 0-7, for the interrupt with the number [4n+2], where n is the number of the Interrupt Priority register (n=0 for PRIO , and so on). The lower the value, the greater the priority of the corresponding interrupt.
20:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:13	INTB	R/W	0x0	Interrupt Priority for Interrupt [4n+1] This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the Interrupt Priority register (n=0 for PRIO , and so on). The lower the value, the greater the priority of the corresponding interrupt.
12:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	INTA	R/W	0x0	Interrupt Priority for Interrupt [4n] This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the Interrupt Priority register (n=0 for PRIO , and so on). The lower the value, the greater the priority of the corresponding interrupt.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 45: Interrupt 64-67 Priority (PRI16), offset 0x440
Register 46: Interrupt 68-71 Priority (PRI17), offset 0x444
Register 47: Interrupt 72-75 Priority (PRI18), offset 0x448
Register 48: Interrupt 76-79 Priority (PRI19), offset 0x44C
Register 49: Interrupt 80-83 Priority (PRI20), offset 0x450
Register 50: Interrupt 84-87 Priority (PRI21), offset 0x454
Register 51: Interrupt 88-91 Priority (PRI22), offset 0x458
Register 52: Interrupt 92-95 Priority (PRI23), offset 0x45C
Register 53: Interrupt 96-99 Priority (PRI24), offset 0x460
Register 54: Interrupt 100-103 Priority (PRI25), offset 0x464
Register 55: Interrupt 104-107 Priority (PRI26), offset 0x468
Register 56: Interrupt 108-111 Priority (PRI27), offset 0x46C
Register 57: Interrupt 112-115 Priority (PRI28), offset 0x470
Register 58: Interrupt 116-119 Priority (PRI29), offset 0x474
Register 59: Interrupt 120-123 Priority (PRI30), offset 0x478
Register 60: Interrupt 124-127 Priority (PRI31), offset 0x47C
Register 61: Interrupt 128-131 Priority (PRI32), offset 0x480

Note: This register can only be accessed from privileged mode.

The **PRIn** registers (see also page 146) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

PRIn Register Bit Field	Interrupt
Bits 31:29	Interrupt [4n+3]
Bits 23:21	Interrupt [4n+2]
Bits 15:13	Interrupt [4n+1]
Bits 7:5	Interrupt [4n]

See Table 2-9 on page 97 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 158) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

31:29	INTD	R/W	0x0	Interrupt Priority for Interrupt [4n+3] This field holds a priority value, 0-7, for the interrupt with the number [4n+3], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
28:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:21	INTC	R/W	0x0	Interrupt Priority for Interrupt [4n+2] This field holds a priority value, 0-7, for the interrupt with the number [4n+2], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
20:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:13	INTB	R/W	0x0	Interrupt Priority for Interrupt [4n+1] This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
12:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	INTA	R/W	0x0	Interrupt Priority for Interrupt [4n] This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 62: Software Trigger Interrupt (SWTRIG), offset 0xF00

Note: Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 97 for interrupt assignments.

When the **MAINPEND** bit in the **Configuration and Control (CFGCTRL)** register (see page 162) is set, unprivileged software can access the **SWTRIG** register.

7:0	INTID	WO	0x00	Interrupt ID This field holds the interrupt ID of the required SGI. For example, a value of 0x3 generates an interrupt on IRQ3.

3.5 System Control Block (SCB) Register Descriptions

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

Register 63: Auxiliary Control (ACTLR), offset 0x008

Note: This register can only be accessed from privileged mode.

The **ACTLR** register provides disable bits for **IT** folding, write buffer use for accesses to the default memory map, and interruption of multi-cycle instructions. By default, this register is set to provide optimum performance from the Cortex-M4 processor and does not normally require modification.

Auxiliary Control (ACTLR)

Base 0xE000.E000

Offset 0x008

Type R/W, reset 0x0000.0000

31:10	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	DISOOF	R/W	0	Disable Out-Of-Order Floating Point Disables floating-point instructions completing out of order with respect to integer instructions.
8	DISFPCA	R/W	0	Disable CONTROL.FPCA Disable automatic update of the FPCA bit in the CONTROL register.
<p>Important: Two bits control when FPCA can be enabled: the ASPEN bit in the Floating-Point Context Control (FPCC) register and the DISFPCA bit in the Auxiliary Control (ACTLR) register.</p>				
7:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DISFOLD	R/W	0	Disable IT Folding
	Value	Description		
	0	No effect.		
	1	Disables IT folding.		

In some situations, the processor can start executing the first instruction in an **IT** block while it is still executing the **IT** instruction. This behavior is called *IT folding*, and improves performance. However, **IT** folding can cause jitter in looping. If a task must avoid jitter, set the **DISFOLD** bit before executing the task, to disable **IT** folding.

Bit/Field	Name	Type	Reset	Description
1	DISWBUF	R/W	0	Disable Write Buffer Value Description 0 No effect. 1 Disables write buffer use during default memory map accesses. In this situation, all bus faults are precise bus faults but performance is decreased because any store to memory must complete before the processor can execute the next instruction. Note: This bit only affects write buffers implemented in the Cortex-M4 processor.
0	DISMCYC	R/W	0	Disable Interrupts of Multiple Cycle Instructions Value Description 0 No effect. 1 Disables interruption of load multiple and store multiple instructions. In this situation, the interrupt latency of the processor is increased because any LDM or STM must complete before the processor can stack the current state and enter the interrupt handler.

Register 64: CPU ID Base (CPUID), offset 0xD00

Note: This register can only be accessed from privileged mode.

The **CPUID** register contains the ARM® Cortex™-M4 processor part number, version, and implementation information.

CPU ID Base (CPUID)

Base 0xE000.E000

Offset 0xD00

Type RO, reset 0x410F.C241

Register 65: Interrupt Control and State (INTCTRL), offset 0xD04

Note: This register can only be accessed from privileged mode.

The **INCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INCTRL**, the effect is unpredictable when writing a 1 to both the **PENDSV** and **UNPENDSV** bits, or writing a 1 to both the **PENDSTSET** and **PENDSTCLR** bits.

Interrupt Control and State (INTCTRL)

Base 0xE000.E000

Offset 0xD04

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31	NMISSET	R/W	0	NMI Set Pending
----	---------	-----	---	-----------------

Value Description

0	On a read, indicates an NMI exception is not pending. On a write, no effect.
---	---

1	On a read, indicates an NMI exception is pending. On a write, changes the NMI exception state to pending.
---	--

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the **NMI** signal is reasserted while the processor is executing that handler.

30:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
-------	----------	----	-----	---

28	PENDSV	R/W	0	PendSV Set Pending
----	--------	-----	---	--------------------

Value Description

0	On a read, indicates a PendSV exception is not pending. On a write, no effect.
---	---

1	On a read, indicates a PendSV exception is pending. On a write, changes the PendSV exception state to pending.
---	---

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the **UNPENDSV** bit.

Bit/Field	Name	Type	Reset	Description
27	UNPENDSV	WO	0	<p>PendSV Clear Pending</p> <p>Value Description</p> <p>0 On a write, no effect.</p> <p>1 On a write, removes the pending state from the PendSV exception.</p> <p>This bit is write only; on a register read, its value is unknown.</p>

Bit/Field	Name	Type	Reset	Description
31:30	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
29	BASE	R/W	0	Vector Table Base Value Description 0 The vector table is in the code memory region. 1 The vector table is in the SRAM memory region.
28:10	OFFSET	R/W	0x000.00	Vector Table Offset When configuring the <i>OFFSET</i> field, the offset must be aligned to the number of exception entries in the vector table. Because there are 131 interrupts, the offset must be aligned on a 1024-byte boundary.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 67: Application Interrupt and Reset Control (APINT), offset 0xD0C

Note: This register can only be accessed from privileged mode.

The **APINT** register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the **VECTKEY** field, otherwise the write is ignored.

The **PRIGROUP** field indicates the position of the binary point that splits the **INTx** fields in the **Interrupt Priority (PRIx)** registers into separate group priority and subpriority fields. Table 3-9 on page 158 shows how the **PRIGROUP** value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the **INTA** field. For the **INTB** field, the corresponding bits are 15:13; for **INTC**, 23:21; and for **INTD**, 31:29.

Note: Determining preemption of an exception uses only the group priority field.

Table 3-9. Interrupt Priority Levels

PRIGROUP Bit Field	Binary Point ^a	Group Priority Field	Subpriority Field	Group Priorities	Subpriorities
0x0 - 0x4	bxxx.	[7:5]	None	8	1
0x5	bxx.y	[7:6]	[5]	4	2
0x6	bx.yy	[7]	[6:5]	2	4
0x7	b.yyy	None	[7:5]	1	8

a. **INTx** field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

Application Interrupt and Reset Control (APINT)

0	reserved	RO	0	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>

Register 69: Configuration and Control (CFGCTRL), offset 0xD14

Note: This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 150).

Configuration and Control (CFGCTRL)

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	STKALIGN	R/W	1	Stack Alignment on Exception Entry Value Description 0 The stack is 4-byte aligned. 1 The stack is 8-byte aligned. On exception entry, the processor uses bit 9 of the stacked PSR to indicate the stack alignment. On return from the exception, it uses this stacked bit to restore the correct stack alignment.
8	BFHFNMIGN	R/W	0	Ignore Bus Fault in NMI and Fault This bit enables handlers with priority -1 or -2 to ignore data bus faults caused by load and store instructions. The setting of this bit applies to the hard fault, NMI, and FAULTMASK escalated handlers. Value Description 0 Data bus faults caused by load and store instructions cause a lock-up. 1 Handlers running at priority -1 and -2 ignore data bus faults caused by load and store instructions. Set this bit only when the handler and its data are in absolutely safe memory. The normal use of this bit is to probe system devices and bridges to detect control path problems and fix them.
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 73: System Handler Control and State (SYSHNDCTRL), offset 0xD24

Note: This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.

If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.

				0 Memory management fault is not active.
				1 Memory management fault is active.
				This bit can be modified to change the active status of the memory management fault exception, however, see the Caution above before setting this bit.

Register 74: Configurable Fault Status (FAULTSTAT), offset 0xD28

Note: This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

FAULTSTAT is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the **MMARV** bit in **MFAULTSTAT**, or the **BFARV** bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

Bit/Field	Name	Type	Reset	Description
31	DBG	R/W1C	0	Debug Event This bit is reserved for Debug use. This bit must be written as a 0, otherwise behavior is unpredictable.
30	FORCED	R/W1C	0	Forced Hard Fault Value Description 0 No forced hard fault has occurred. 1 A forced hard fault has been generated by escalation of a fault with configurable priority that cannot be handled, either because of priority or because it is disabled. When this bit is set, the hard fault handler must read the other fault status registers to find the cause of the fault. This bit is cleared by writing a 1 to it.
29:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	VECT	R/W1C	0	Vector Table Read Fault Value Description 0 No bus fault has occurred on a vector table read. 1 A bus fault occurred on a vector table read. This error is always handled by the hard fault handler. When this bit is set, the PC value stacked for the exception return points to the instruction that was preempted by the exception. This bit is cleared by writing a 1 to it.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 76: Memory Management Fault Address (MMADDR), offset 0xD34

Note: This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 171).

Memory Management Fault Address (MMADDR)

Base 0xE000.E000

Offset 0xD34

3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

Register 78: MPU Type (MPUTYPE), offset 0xD90

Note: This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

MPU Type (MPUTYPE)

Base 0xE000.E000

Offset 0xD90

Type RO, reset 0x0000.0800

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved								IREGION							
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:16	IREGION	RO	0x00	Number of I Regions This field indicates the number of supported MPU instruction regions. This field always contains 0x00. The MPU memory map is unified and is described by the DREGION field.
15:8	DREGION	RO	0x08	Number of D Regions Value Description 0x08 Indicates there are eight supported MPU data regions.
7:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	SEPARATE	RO	0	Separate or Unified MPU Value Description 0 Indicates the MPU is unified.

Register 79: MPU Control (MPUCTRL), offset 0xD94

Note: This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the **ENABLE** and **PRIVDEFEN** bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 85. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the **ENABLE** bit.

When the **ENABLE** bit is set, at least one region of the memory map must be enabled for the system to function unless the **PRIVDEFEN** bit is set. If the **PRIVDEFEN** bit is set and no regions are enabled, then only privileged software can operate.

When the **ENABLE** bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 88 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether **PRIVDEFEN** is set.

Unless **HFNMIENA** is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the **HFNMIENA** bit enables the MPU when operating with these two priorities.

Register 80: MPU Region Number (MPUNUMBER), offset 0xD98

Note: This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the **VALID** bit set (see page 184). This write updates the value of the **REGION** field.

MPU Region Number (MPUNUMBER)

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	NUMBER	R/W	0x0	MPU Region to Access This field indicates the MPU region referenced by the MPUBASE and MPUATTR registers. The MPU supports eight memory regions.

Register 81: MPU Region Base Address (MPUBASE), offset 0xD9C

Register 82: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4

Register 83: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC

Register 84: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4

Note: This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:*N* of the **MPUBASE** register. Bits (*N*-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of *N* where:

$$N = \text{Log}_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

MPU Region Base Address (MPUBASE)

Base 0xE000.E000

Offset 0xD9C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	ADDR	R/W	0x0000.000	Base Address Mask Bits 31: <i>N</i> in this field contain the region base address. The value of <i>N</i> depends on the region size, as shown above. The remaining bits (<i>N</i> -1):5 are reserved. Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
4	VALID	WO	0	Region Number Valid Value Description 0 The MPUNUMBER register is not changed and the processor updates the base address for the region specified in the MPUNUMBER register and ignores the value of the REGION field. 1 The MPUNUMBER register is updated with the value of the REGION field and the base address is updated for the region specified in the REGION field. This bit is always read as 0.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	REGION	R/W	0x0	Region Number On a write, contains the value to be written to the MPUNUMBER register. On a read, returns the current region number in the MPUNUMBER register.

Register 85: MPU Region Attribute and Size (MPUATTR), offset 0xDA0

Register 86: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8

Register 87: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0

Register 88: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8

Note: This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, **XN**, **AP**, **TEX**, **S**, **C**, and **B**, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The **SIZE** field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a **SIZE** value of 4. Table 3-10 on page 186 gives example **SIZE** values with the corresponding region size and value of **N** in the **MPU Region Base Address (MPUBASE)** register.

Table 3-10. Example SIZE Field Values

SIZE Encoding	Region Size	Value of N ^a	Note
00100b (0x4)	32 B	5	Minimum permitted size
01001b (0x9)	1 KB	10	-
10011b (0x13)	1 MB	20	-
11101b (0x1D)	1 GB	30	-
11111b (0x1F)	4 GB	No valid ADDR field in MPUBASE ; the region occupies the complete memory map.	Maximum possible size

a. Refers to the N parameter in the **MPUBASE** register (see page 184).

Region sizes of 128 bytes and less do not support subregions. When writing the attributes for such a region, configure the SRD field as 0x00. See the section called "Subregions" on page 122 for more information.
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:1	SIZE	R/W	0x0	Region Size Mask The SIZE field defines the size of the MPU memory region specified by the MPUNUMBER register. Refer to Table 3-10 on page 186 for more information.

Bit/Field	Name	Type	Reset	Description
0	ENABLE	R/W	0	Region Enable
				Value Description
			0	The region is disabled.
			1	The region is enabled.

3.7 Floating-Point Unit (FPU) Register Descriptions

This section lists and describes the Floating-Point Unit (FPU) registers, in numerical order by address offset.

Register 89: Coprocessor Access Control (CPAC), offset 0xD88

The **CPAC** register specifies the access privileges for coprocessors.

Coprocessor Access Control (CPAC)

Base 0xE000.E000

Offset 0xD88

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved								CP11		CP10		reserved			
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:22	CP11	R/W	0x00	CP11 Coprocessor Access Privilege Value Description 0x0 Access Denied Any attempted access generates a NOCP Usage Fault. 0x1 Privileged Access Only An unprivileged access generates a NOCP fault. 0x2 Reserved The result of any access is unpredictable. 0x3 Full Access
21:20	CP10	R/W	0x00	CP10 Coprocessor Access Privilege Value Description 0x0 Access Denied Any attempted access generates a NOCP Usage Fault. 0x1 Privileged Access Only An unprivileged access generates a NOCP fault. 0x2 Reserved The result of any access is unpredictable. 0x3 Full Access
19:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 90: Floating-Point Context Control (FPCC), offset 0xF34The **FPCC** register sets or returns FPU control data.

Floating-Point Context Control (FPCC)

Base 0xE000.E000

Offset 0xF34

Type R/W, reset 0xC000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Stellaris[®] JTAG controller works with the ARM JTAG controller built into the Cortex-M4F core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Stellaris JTAG instructions select the Stellaris TDO output. The multiplexer is controlled by the Stellaris JTAG controller, which has comprehensive programming for the ARM, Stellaris, and unimplemented JTAG instructions.

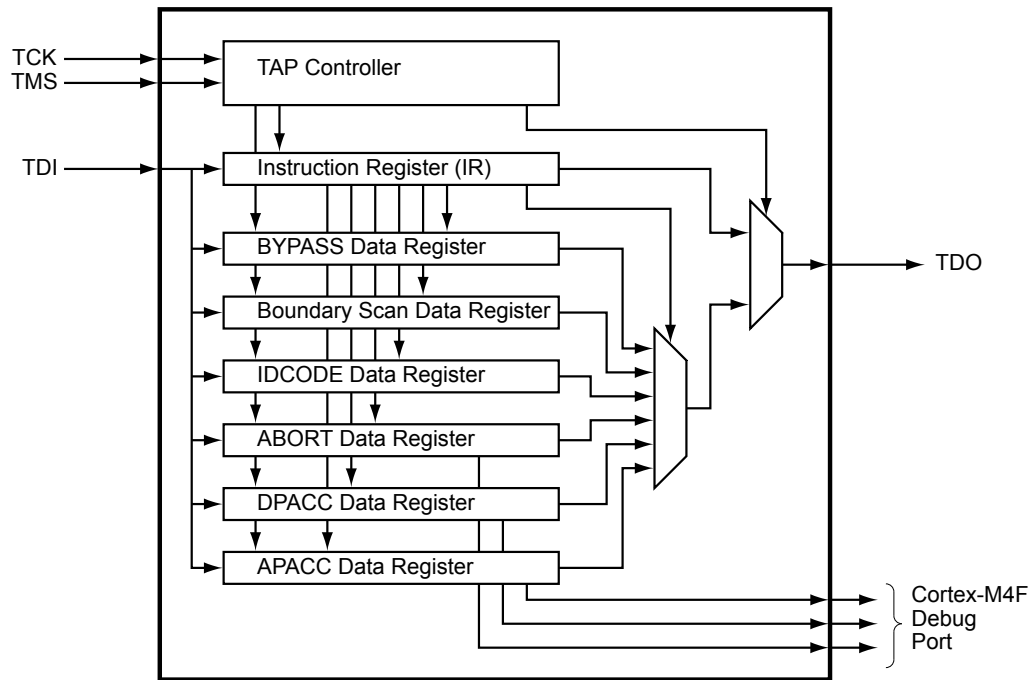

The Stellaris JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Embedded Trace Macrocell (ETM) for instruction trace capture
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM[®] Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

4.2 Signal Description

The following table lists the external signals of the JTAG/SWD controller and describes the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 652. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOPTCL)** register (page 683) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 645.

Table 4-1. Signals for JTAG_SWD_SWO (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
SWCLK	52	PC0 (1)	I	TTL	JTAG/SWD CLK.
SWDIO	51	PC1 (1)	I/O	TTL	JTAG TMS and SWDIO.
SWO	49	PC3 (1)	O	TTL	JTAG TDO and SWO.
TCK	52	PC0 (1)	I	TTL	JTAG/SWD CLK.
TDI	50	PC2 (1)	I	TTL	JTAG TDI.
TDO	49	PC3 (1)	O	TTL	JTAG TDO and SWO.

Table 4-1. Signals for JTAG_SWD_SWO (64LQFP) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
TMS	51	PC1 (1)	I	TTL	JTAG TMS and SWDIO.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

4.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 195. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 4-3 on page 202 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1169 for JTAG timing diagrams.

Note: Of all the possible reset sources, only Power-On reset (POR) and the assertion of the $\overline{\text{RST}}$ input have any effect on the JTAG module. The pin configurations are reset by both the $\overline{\text{RST}}$ input and POR, whereas the internal JTAG logic is only reset with POR. See “Reset Sources” on page 207 for more information on reset.

4.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated state after a power-on reset or reset caused by the $\overline{\text{RST}}$ input are given in Table 4-2. Detailed information on each pin follows. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 645 for information on how to reprogram the configuration of these pins.

Table 4-2. JTAG Port Pins State after Power-On Reset or $\overline{\text{RST}}$ assertion

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

4.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components.

During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 672 and page 674).

4.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 198.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 672).

4.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 672).

4.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 672 and page 674).

4.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset

the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 4-2. Test Access Port State Machine

4.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller’s CAPTURE states and allows this information to be shifted out on TDO during the TAP controller’s SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller’s UPDATE states. Each of the shift registers is discussed in detail in “Register Descriptions” on page 201.

4.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

4.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or $\overline{\text{RST}}$, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality ($\text{DEN}[3:0]$ set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors ($\text{PUE}[3:0]$ set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors ($\text{PDE}[3:0]$ cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the alternate hardware function ($\text{AFSEL}[3:0]$ set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 666, page 672, page 674, and page 677.

It is possible for software to configure these pins as GPIOs after reset by clearing $\text{AFSEL}[3:0]$ in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins ($\text{PC}[3:0]$) and the NMI pin (PD7 and PF0). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 666), **GPIO Pull Up Select (GPIOPUR)** register (see page 672), **GPIO Pull-Down Select (GPIOPDR)** register (see page 674), and **GPIO Digital Enable (GPIODEN)** register (see page 677) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 679) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 680) have been set.

4.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (TCK or SWCLK), the previous operation has enough time to complete and the ACK bits do not have to be checked.

4.3.4.3 Recovering a "Locked" Microcontroller

Note: Performing the sequence below restores the non-volatile registers discussed in “Non-Volatile Register Programming” on page 532 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the non-volatile registers being restored.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug port unlock sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The debug port unlock sequence is:

1. Assert and hold the $\overline{\text{RST}}$ signal.

2. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 200.
3. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 201.
4. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
5. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
6. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
7. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
8. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
9. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
10. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
11. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
12. Release the $\overline{\text{RST}}$ signal.
13. Wait 400 ms.
14. Power-cycle the microcontroller.

4.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M4F core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

JTAG-to-SWD Switching

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first.

This command can also be represented as 0xE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode, the SWD goes into the line reset state before sending the switch sequence.

SWD-to-JTAG Switching

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode, the JTAG goes into the Test Logic Reset state before sending the switch sequence.

4.4 Initialization and Configuration

After a Power-On-Reset or an external reset (\overline{RST}), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins (PC[3:0]) should be returned to their default settings.

4.5 Register Descriptions

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

4.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 4-3. A detailed explanation of each instruction, along with its associated Data Register, follows.

Table 4-3. JTAG Instruction Register Commands

IR[3:0]	Instruction	Description
0x0	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0x1	INTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.
0x2	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
0x8	ABORT	Shifts data into the ARM Debug Port Abort Register.
0xA	DPACC	Shifts data into and out of the ARM DP Access Register.
0xB	APACC	Shifts data into and out of the ARM AC Access Register.
0xE	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
0xF	BYPASS	Connects TDI to TDO through a single Shift Register chain.
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

4.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

4.5.1.2 INTEST Instruction

The INTEST instruction is not associated with its own Data Register chain. Instead, the INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. With tests that drive known values into the controller, this instruction can be used for testing. It is important to note that although the RST input pin is on the Boundary Scan Data Register chain, it is only observable. While the INTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

4.5.1.3 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. See “Boundary Scan Data Register” on page 204 for more information.

4.5.1.4 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 205 for more information.

4.5.1.5 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 205 for more information.

4.5.1.6 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 205 for more information.

4.5.1.7 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 204 for more information.

4.5.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 204 for more information.

4.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

4.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M4F during debug.

Figure 4-3. IDCODE Register Format

4.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

Figure 4-4. BYPASS Register Format

4.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. The EXTEST instruction forces data out of the controller, and the INTEST instruction forces data into the controller.

Figure 4-5. Boundary Scan Register Format

4.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

4.5.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

4.5.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

5 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

5.1 Signal Description

The following table lists the external signals of the System Control module and describes the function of each. The **NMI** signal is the alternate function for two GPIO signals and functions as a GPIO after reset. **PD7** and **PF0** are under commit protection and require a special process to be configured as any alternate function or to subsequently return to the GPIO function, see “Commit Control” on page 652. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the **NMI** signal. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the NMI function. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOPTL)** register (page 683) to assign the **NMI** signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 645. The remaining signals (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 5-1. Signals for System Control & Clocks (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
NMI	10 28	PD7 (8) PF0 (8)	I	TTL	Non-maskable interrupt.
OSC0	40	fixed	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	41	fixed	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
$\overline{\text{RST}}$	38	fixed	I	TTL	System reset input.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

5.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 206
- Local control, such as reset (see “Reset Control” on page 207), power (see “Power Control” on page 212) and clock control (see “Clock Control” on page 213)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 220

5.2.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, memory sizes, and peripherals present on the device. The **Device Identification 0 (DID0)** (page 229) and **Device Identification 1 (DID1)** (page 231) registers provide details about the device's version, package, temperature range, and so on. The Peripheral Present registers starting at System Control offset 0x300, such as the **Watchdog Timer Peripheral Present (PPWD)** register, provide information on how many of each type of module are included on the device. Finally,

information about the capabilities of the on-chip peripherals are provided at offset 0xFC0 in each peripheral's register space in the Peripheral Properties registers, such as the **GPTM Peripheral Properties (GPTMPP)** register. Previous generations of Stellaris® devices used the **Device Capabilities (DC0-DC9)** registers for information about the peripherals and their capabilities. These registers are present on this device for backward software capability, but provide no information about peripherals that were not available on older devices.

5.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

5.2.2.1 Reset Sources

The LM4F120B2QR microcontroller has six sources of reset:

1. Power-on reset (POR) (see page 208).
2. External reset input pin (\overline{RST}) assertion (see page 208).
3. Internal brown-out (BOR) detector (see page 210).
4. Software-initiated reset (with the software reset registers) (see page 210).
5. A watchdog timer reset condition violation (see page 211).
6. MOSC failure (see page 212).

Table 5-2 provides a summary of results of the various reset operations.

Table 5-2. Reset Sources

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset?
Power-On Reset	Yes	Yes	Yes
\overline{RST}	Yes	Pin Config Only	Yes
Brown-Out Reset	Yes	Pin Config Only	Yes
Software System Request Reset using the <code>SYSRESREQ</code> bit in the <code>APINT</code> register.	Yes	Pin Config Only	Yes
Software System Request Reset using the <code>VECTRESET</code> bit in the <code>APINT</code> register.	Yes	Pin Config Only	No
Software Peripheral Reset	No	Pin Config Only	Yes ^a
Watchdog Reset	Yes	Pin Config Only	Yes
MOSC Failure Reset	Yes	Pin Config Only	Yes

a. Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, in which case, all the bits in the **RESC** register are cleared except for the POR indicator. A bit in the **RESC** register can be cleared by writing a 0.

At any reset that resets the core, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal as configured in the **Boot Configuration (BOOTCFG)** register.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If then **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

For example, if the **BOOTCFG** register is written and committed with the value of 0x0000.3C01, then **PB7** is examined at reset to determine if the ROM Boot Loader should be executed. If **PB7** is Low, the core unconditionally begins executing the ROM boot loader. If **PB7** is High, then the application in Flash memory is executed if the reset vector at location 0x0000.0004 is not 0xFFFF.FFFF. Otherwise, the ROM boot loader is executed.

5.2.2.2 Power-On Reset (POR)

Note: The JTAG controller can only be reset by the power-on reset.

The internal Power-On Reset (POR) circuit monitors the power supply voltage (V_{DD}) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value (V_{TH}). The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete (see “Power and Brown-Out” on page 1170). For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the \overline{RST} input may be used as discussed in “External \overline{RST} Pin” on page 208.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller and when the microcontroller wakes from hibernation. The Power-On Reset timing is shown in Figure 23-4 on page 1171.

5.2.2.3 External \overline{RST} Pin

Note: It is recommended that the trace for the \overline{RST} signal must be kept as short as possible. Be sure to place any components connected to the \overline{RST} signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the \overline{RST} input must be connected to the power supply (V_{DD}) through an optional pull-up resistor (0 to 100K Ω) as shown in Figure 5-1 on page 209. The \overline{RST} input has filtering which requires a minimum pulse width in order for the reset pulse to be recognized, see Table 23-7 on page 1171.

Figure 5-1. Basic $\overline{\text{RST}}$ Configuration

$R_{PU} = 0$ to $100\text{ k}\Omega$

The external reset pin ($\overline{\text{RST}}$) resets the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin ($\overline{\text{RST}}$) is asserted for the duration specified by T_{MIN} and then de-asserted (see "Reset" on page 1171).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

To improve noise immunity and/or to delay reset at power up, the $\overline{\text{RST}}$ input may be connected to an RC network as shown in Figure 5-2 on page 209.

Figure 5-2. External Circuitry to Extend Power-On Reset

$R_{PU} = 1\text{ k}\Omega$ to $100\text{ k}\Omega$

$C_1 = 1\text{ nF}$ to $10\text{ }\mu\text{F}$

If the application requires the use of an external reset switch, Figure 5-3 on page 210 shows the proper circuitry to use.

Figure 5-3. Reset Circuit Controlled by Switch

Typical $R_{\text{PU}} = 10 \text{ k}\Omega$

Typical $R_S = 470 \Omega$

$C_1 = 10 \text{ nF}$

The R_{PU} and C_1 components define the power-on delay.

The external reset timing is shown in Figure 23-6 on page 1172.

5.2.2.4 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the power supply (V_{DD}) drops below a brown-out threshold voltage (V_{BTH}). If a brown-out condition is detected, the system may generate an interrupt or a system reset. The default condition is to generate an interrupt, so BOR must be enabled. Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The BORIOR bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset; if BORIOR is clear, an interrupt is generated.

The brown-out reset sequence is as follows:

1. When V_{DD} drops below V_{BTH} , an internal BOR condition is set.
2. If the BOR condition exists, an internal reset is asserted.
3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The result of a brown-out reset is equivalent to that of an assertion of the external $\overline{\text{RST}}$ input, and the reset is held active until the proper V_{DD} level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 23-5 on page 1171.

5.2.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via peripheral-specific reset registers available beginning at System Control offset 0x500 (for example the **Watchdog Timer Software Reset (SRWD)** register). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset.

The entire microcontroller, including the core, can be reset by software by setting the `SYSRESREQ` bit in the **Application Interrupt and Reset Control (APINT)** register. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the `SYSRESREQ` bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The core only can be reset by software by setting the `VECTRESET` bit in the **APINT** register. The software-initiated core reset sequence is as follows:

1. A core reset is initiated by setting the `VECTRESET` bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 23-7 on page 1172.

5.2.2.6 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The LM4F120B2QR microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). Each module operates in the same manner except that because the PIOSC watchdog timer module is in a different clock domain, register accesses must have a time delay between them. The watchdog timer can be configured to generate an interrupt or a non-maskable interrupt to the microcontroller on its first time-out and to generate a reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the microcontroller. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see "Watchdog Timers" on page 768.

The watchdog reset timing is shown in Figure 23-8 on page 1172.

5.2.3 Non-Maskable Interrupt

The microcontroller has four sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal
- A main oscillator verification error
- The NMISET bit in the **Interrupt Control and State (INTCTRL)** register in the Cortex™-M4F (see page 154).
- The Watchdog module time-out interrupt when the INTTYPE bit in the **Watchdog Control (WDTCTL)** register is set (see page 774).

Software must check the cause of the interrupt in order to distinguish among the sources.

5.2.3.1 NMI Pin

The NMI signal is an alternate function for either GPIO port pin PD7 or PF0. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 645. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality, see page 680. The active sense of the NMI signal is High; asserting the enabled NMI signal above V_{IH} initiates the NMI interrupt sequence.

5.2.3.2 Main Oscillator Verification Failure

The LM4F120B2QR microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. If the main oscillator verification circuit is enabled and a failure occurs, either a power-on reset is generated and control is transferred to the NMI handler, or an interrupt is generated. The MOSCIM bit in the **MOSCCTL** register determines which action occurs. In either case, the system clock source is automatically switched to the PIOSC. If a MOSC failure reset occurs, the NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Main Oscillator Verification Circuit” on page 219.

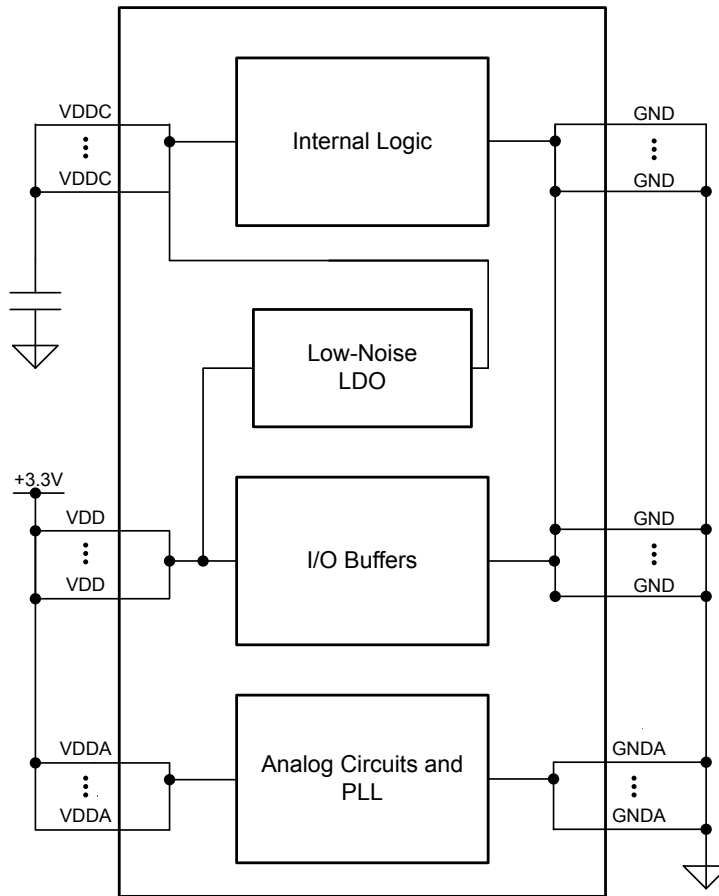

5.2.4 Power Control

The Stellaris microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. Figure 5-4 shows the power architecture.

An external LDO may not be used.

Note: VDDA must be supplied with 3.3 V, or the microcontroller does not function properly. VDDA is the supply for all of the analog circuitry on the device, including the clock circuitry.

Figure 5-4. Power Architecture

5.2.5 Clock Control

System control determines the control of clocks in this part.

5.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller:

- Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source that is the clock source the microcontroller uses during and following POR. It does not require the use of any external components and provides a clock that is 16 MHz \pm 1% at room temperature and \pm 3% across temperature. The PIOSC allows for a reduced system cost in applications that require an accurate clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference. If the Hibernation Module clock source is a 32.768-kHz oscillator, the precision internal oscillator can be trimmed by software based on a reference clock for increased accuracy. Regardless of whether or not the PIOSC is the source for the system clock, the PIOSC can be configured to be the source for the ADC clock as well as the baud clock for the UART and SSI, see “System Control” on page 220.
- Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or

an external crystal is connected across the `OSC0` input and `OSC1` output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 5 MHz to 25 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 4 MHz to 25 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller. The supported crystals are listed in the `XTAL` bit field in the **RCC** register (see page 272). Note that the MOSC provides the clock source for the USB PLL and must be connected to a crystal or an oscillator.

- **Internal 30-kHz Oscillator.** The internal 30-kHz oscillator provides an operational frequency of 30 kHz \pm 50%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the MOSC to be powered down.
- **Hibernation Module Clock Source.** The Hibernation module is clocked by a 32.768-kHz oscillator connected to the `XOSC0` pin. The 32.768-kHz oscillator can be used for the system clock, thus eliminating the need for an additional crystal or oscillator. The Hibernation module clock source is intended to provide the system with a real-time clock source and may also provide an accurate source of Deep-Sleep or Hibernate mode power savings.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL and the precision internal oscillator divided by four (4 MHz \pm 1%). The frequency of the PLL clock reference must be in the range of 5 MHz to 25 MHz (inclusive). Table 5-3 on page 214 shows how the various clock sources can be used in a system.

Table 5-3. Clock Source Options

Clock Source	Drive PLL?		Used as SysClk?	
Precision Internal Oscillator	Yes	BYPASS = 0, OSCSRC = 0x1	Yes	BYPASS = 1, OSCSRC = 0x1
Precision Internal Oscillator divide by 4 (4 MHz \pm 1%)	No	-	Yes	BYPASS = 1, OSCSRC = 0x2
Main Oscillator	Yes	BYPASS = 0, OSCSRC = 0x0	Yes	BYPASS = 1, OSCSRC = 0x0
Internal 30-kHz Oscillator	No	-	Yes	BYPASS = 1, OSCSRC = 0x3
Hibernation Module 32.768-kHz Oscillator	No	-	Yes	BYPASS = 1, OSCSRC2 = 0x7

5.2.5.2 Clock Configuration

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options. These registers control the following clock functionality:

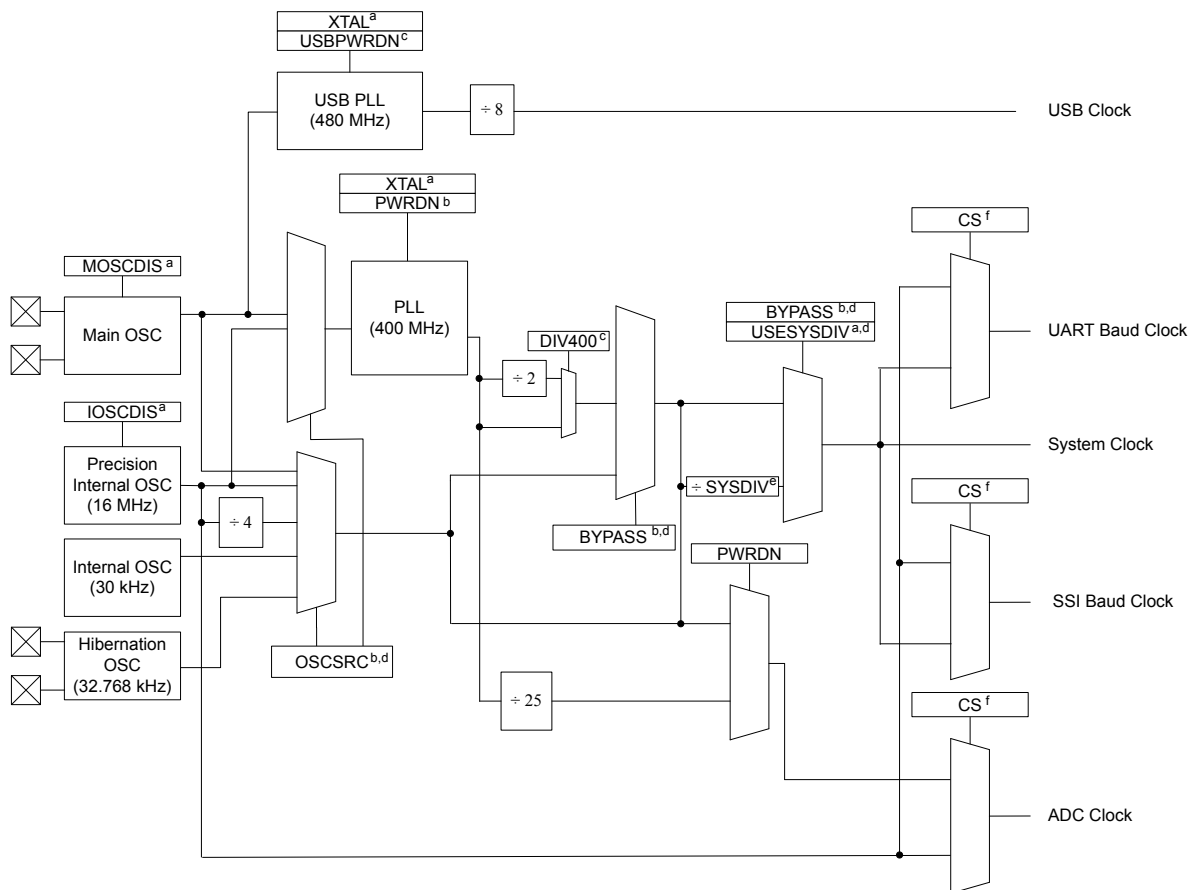

- Source of clocks in sleep and deep-sleep modes
- System clock derived from PLL or other clock source
- Enabling/disabling of oscillators and PLL
- Clock divisors
- Crystal input selection

Important: Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

Figure 5-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal can be selected from the PIOSC, the system clock if the PLL is disabled, or the PLL output divided down to 16 MHz if the PLL is enabled.

Note: If the ADC module is not using the PIOSC as the clock source, the system clock must be at least 16 MHz. When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz.

Figure 5-5. Main Clock Tree

- a. Control provided by **RCC** register bit/field.
 b. Control provided by **RCC** register bit/field or **RCC2** register bit/field, if overridden with **RCC2** register bit **USERCC2**.
 c. Control provided by **RCC2** register bit/field.
 d. Also may be controlled by **DSLPCLKCFG** when in deep sleep mode.
 e. Control provided by **RCC** register **SYSDIV** field, **RCC2** register **SYSDIV2** field if overridden with **USERCC2** bit, or **[SYSDIV2,SYSDIV2LSB]** if both **USERCC2** and **DIV400** bits are set.
 f. Control provided by **UARTCC**, **SSICC**, and **ADCC** register field.

Communication Clock Sources

In addition to the main clock tree described above, the UART, CAN, and SSI modules all have a Clock Control register in the peripheral's register map at offset 0xFC8 that can be used to select

the clock source for the module's baud clock. Users can choose between the system clock, which is the default source for the baud clock, and the PIOSC. Note that there may be special considerations when using the PIOSC as the baud clock. For more information, see the Clock Control register description in the chapter describing the operation of the module.

Using the SYSDIV and SYSDIV2 Fields

In the **RCC** register, the **SYSDIV** field specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the **BYPASS** bit in this register is configured). When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. Table 5-4 shows how the **SYSDIV** encoding affects the system clock frequency, depending on whether the PLL is used (**BYPASS**=0) or another clock source is used (**BYPASS**=1). The divisor is equivalent to the **SYSDIV** encoding plus 1. For a list of possible clock sources, see Table 5-3 on page 214.

Table 5-4. Possible System Clock Frequencies Using the SYSDIV Field

SYSDIV	Divisor	Frequency (BYPASS=0)	Frequency (BYPASS=1)	StellarisWare® Parameter ^a
0x0	/1	reserved	Clock source frequency/2	SYSCCTL_SYSDIV_1 ^b
0x1	/2	reserved	Clock source frequency/2	SYSCCTL_SYSDIV_2
0x2	/3	66.67 MHz	Clock source frequency/3	SYSCCTL_SYSDIV_3
0x3	/4	50 MHz	Clock source frequency/4	SYSCCTL_SYSDIV_4
0x4	/5	40 MHz	Clock source frequency/5	SYSCCTL_SYSDIV_5
0x5	/6	33.33 MHz	Clock source frequency/6	SYSCCTL_SYSDIV_6
0x6	/7	28.57 MHz	Clock source frequency/7	SYSCCTL_SYSDIV_7
0x7	/8	25 MHz	Clock source frequency/8	SYSCCTL_SYSDIV_8
0x8	/9	22.22 MHz	Clock source frequency/9	SYSCCTL_SYSDIV_9
0x9	/10	20 MHz	Clock source frequency/10	SYSCCTL_SYSDIV_10
0xA	/11	18.18 MHz	Clock source frequency/11	SYSCCTL_SYSDIV_11
0xB	/12	16.67 MHz	Clock source frequency/12	SYSCCTL_SYSDIV_12
0xC	/13	15.38 MHz	Clock source frequency/13	SYSCCTL_SYSDIV_13
0xD	/14	14.29 MHz	Clock source frequency/14	SYSCCTL_SYSDIV_14
0xE	/15	13.33 MHz	Clock source frequency/15	SYSCCTL_SYSDIV_15
0xF	/16	12.5 MHz (default)	Clock source frequency/16	SYSCCTL_SYSDIV_16

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCCTL_SYSDIV_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

The **SYSDIV2** field in the **RCC2** register is 2 bits wider than the **SYSDIV** field in the **RCC** register so that additional larger divisors up to /64 are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. The divisor is equivalent to the **SYSDIV2** encoding plus 1. Table 5-5 shows how the **SYSDIV2** encoding affects the system clock frequency, depending on whether the PLL is used (**BYPASS2**=0) or another clock source is used (**BYPASS2**=1). For a list of possible clock sources, see Table 5-3 on page 214.

Table 5-5. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field

SYSDIV2	Divisor	Frequency (BYPASS2=0)	Frequency (BYPASS2=1)	StellarisWare Parameter ^a
0x00	/1	reserved	Clock source frequency/2	SYSCCTL_SYSDIV_1 ^b

Table 5-5. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field (continued)

SYSDIV2	Divisor	Frequency (BYPASS2=0)	Frequency (BYPASS2=1)	StellarisWare Parameter ^a
0x01	/2	reserved	Clock source frequency/2	SYSCCTL_SYSDIV_2
0x02	/3	66.67 MHz	Clock source frequency/3	SYSCCTL_SYSDIV_3
0x03	/4	50 MHz	Clock source frequency/4	SYSCCTL_SYSDIV_4
0x04	/5	40 MHz	Clock source frequency/5	SYSCCTL_SYSDIV_5
...
0x09	/10	20 MHz	Clock source frequency/10	SYSCCTL_SYSDIV_10
...
0x3F	/64	3.125 MHz	Clock source frequency/64	SYSCCTL_SYSDIV_64

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCCTL_SYSDIV_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

To allow for additional frequency choices when using the PLL, the DIV400 bit is provided along with the SYSDIV2LSB bit. When the DIV400 bit is set, bit 22 becomes the LSB for SYSDIV2. In this situation, the divisor is equivalent to the (SYSDIV2 encoding with SYSDIV2LSB appended) plus one. Table 5-6 shows the frequency choices when DIV400 is set. When the DIV400 bit is clear, SYSDIV2LSB is ignored, and the system clock frequency is determined as shown in Table 5-5 on page 216.

Table 5-6. Examples of Possible System Clock Frequencies with DIV400=1

SYSDIV2	SYSDIV2LSB	Divisor	Frequency (BYPASS2=0) ^a	StellarisWare Parameter ^b
0x00	reserved	/2	reserved	-
0x01	0	/3	reserved	-
	1	/4	reserved	-
0x02	0	/5	80 MHz	SYSCCTL_SYSDIV_2_5
	1	/6	66.67 MHz	SYSCCTL_SYSDIV_3
0x03	0	/7	reserved	-
	1	/8	50 MHz	SYSCCTL_SYSDIV_4
0x04	0	/9	44.44 MHz	SYSCCTL_SYSDIV_4_5
	1	/10	40 MHz	SYSCCTL_SYSDIV_5
...
0x3F	0	/127	3.15 MHz	SYSCCTL_SYSDIV_63_5
	1	/128	3.125 MHz	SYSCCTL_SYSDIV_64

a. Note that DIV400 and SYSDIV2LSB are only valid when BYPASS2=0.

b. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

5.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC must remain enabled as it is used for internal functions. The PIOSC can only be disabled during Deep-Sleep mode. It can be powered down by setting the IOSCDIS bit in the **RCC** register.

The PIOSC generates a 16-MHz clock with a $\pm 1\%$ accuracy at room temperatures. Across the extended temperature range, the accuracy is $\pm 3\%$. At the factory, the PIOSC is set to 16 MHz at

room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in one of three ways:

- **Default calibration:** clear the `UTEN` bit and set the `UPDATE` bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- **User-defined calibration:** The user can program the `UT` value to adjust the `PIOSC` frequency. As the `UT` value increases, the generated period increases. To commit a new `UT` value, first set the `UTEN` bit, then program the `UT` field, and then set the `UPDATE` bit. The adjustment finishes within a few clock periods and is glitch free.
- **Automatic calibration using the enable 32.768-kHz oscillator from the Hibernation module:** Set the `CAL` bit in the **PIOSCCAL** register; the results of the calibration are shown in the `RESULT` field in the **Precision Internal Oscillator Statistic (PIOSCSTAT)** register. After calibration is complete, the `PIOSC` is trimmed using the trimmed value returned in the `CT` field.

5.2.5.4 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals form 4 to 25 MHz.

The `XTAL` bit in the **RCC** register (see page 272) describes the available crystal choices and default programming values.

Software configures the **RCC** register `XTAL` field with the crystal number. If the PLL is used in the design, the `XTAL` field value is internally translated to the PLL settings.

5.2.5.5 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the main PLL to drive the output. The PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor, unless the `DIV400` bit in the **RCC2** register is set.

To configure the `PIOSC` to be the clock source for the main PLL, program the `OSCR2` field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x1.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 318). The internal translation provides a translation within $\pm 1\%$ of the targeted PLL VCO frequency. Table 23-10 on page 1173 shows the actual PLL frequency and error for a given crystal choice.

The Crystal Value field (`XTAL`) in the **Run-Mode Clock Configuration (RCC)** register (see page 272) describes the available crystal choices and default programming of the **PLLREQn** registers. Any time the `XTAL` field changes, the new settings are translated and the internal PLL settings are updated.

5.2.5.6 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the `USBPWRDN` bit of the **RCC2** register. The `XTAL` bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 5, 6, 8, 10, 12, 16, 18, 20, 24, or 25 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

5.2.5.7 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 272 and page 278).

5.2.5.8 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is T_{READY} (see Table 23-9 on page 1173). During the relock time, the affected PLL is not usable as a clock reference. Software can poll the **LOCK** bit in the **PLL Status (PLLSTAT)** register to determine when the PLL has locked.

Either PLL is changed by one of the following:

- Change to the **XTAL** value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter clocked by the system clock is used to measure the T_{READY} requirement. The down counter is set to 0x200 if the PLL is powering up. If the M or N values in the **PLLREQn** registers are changed, the counter is set to 0xC0. Hardware is provided to keep the PLL from being used as a system clock until the T_{READY} condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the microcontroller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable (T_{READY} time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the **PLLRLIS** bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time (T_{READY}), and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the T_{READY} period has passed, including periodically polling the **USBPLLRLIS** bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

5.2.5.9 Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the **CVAL** bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, and if the **MOSCIM** bit in the **MOSCCTL** register is clear, then the following sequence is performed by the hardware:

1. The **MOSCFAIL** bit in the **Reset Cause (RESC)** register is set.
2. The system clock is switched from the main oscillator to the **PIOSC**.

3. An internal power-on reset is initiated.
4. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

if the `MOSCIM` bit in the `MOSCCTL` register is set, then the following sequence is performed by the hardware:

1. The system clock is switched from the main oscillator to the `PIOSC`.
2. The `MOFRIS` bit in the `RIS` register is set to indicate a MOSC failure.

5.2.6 System Control

For power-savings purposes, the peripheral-specific `RCGCx`, `SCGCx`, and `DCGCx` registers (for example, `RCGCWD`) control the clock gating logic for that peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. These registers are located in the System Control register map starting at offsets `0x600`, `0x700`, and `0x800`, respectively. There must be a delay of 3 system clocks after a peripheral module clock is enabled in the `RCGC` register before any module registers are accessed.

Important: To support legacy software, the `RCGCn`, `SCGCn`, and `DCGCn` registers are available at offsets `0x100` - `0x128`. A write to any of these legacy registers also writes the corresponding bit in the peripheral-specific `RCGCx`, `SCGCx`, and `DCGCx` registers. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. It is recommended that new software use the new registers and not rely on legacy operation.

If software uses a peripheral-specific register to write a legacy peripheral (such as `TIMER0`), the write causes proper operation, but the value of that bit is not reflected in the legacy register. Any bits that are changed by writing to a legacy register can be read back correctly with a read of the legacy register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

There are four levels of operation for the microcontroller defined as:

- Run mode
- Sleep mode
- Deep-Sleep mode
- Hibernation mode

The following sections describe the different modes in detail.

Caution – If the Cortex-M4F Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their Run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

5.2.6.1 Run Mode

In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the the peripheral-specific **RCGC** registers. The system clock can be any of the available clock sources including the PLL.

5.2.6.2 Sleep Mode

In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M4F core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 107 for more details.

Peripherals are clocked that are enabled in the the peripheral-specific **SCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the the peripheral-specific **RCGC** registers when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

Important: Before executing the WFI instruction, software must confirm that the EEPROM is not busy by checking to see that the **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear.

5.2.6.3 Deep-Sleep Mode

In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first setting the **SLEEPDEEP** bit in the **System Control (SYSCTRL)** register (see page 160) and then executing a WFI instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 107 for more details.

The Cortex-M4F processor core and the memory subsystem are not clocked in Deep-Sleep mode. Peripherals are clocked that are enabled in the the peripheral-specific **DCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the the peripheral-specific **RCGC** registers when auto-clock gating is disabled. The system clock source is specified in the **DSLPCCLKCFG** register. When the **DSLPCCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the WFI instruction, hardware powers the PLL down and overrides the **SYSDIV** field of the active **RCC/RCC2** register, to be determined by the **DSDIVORIDE** setting in the **DSLPCCLKCFG** register, up to /16 or /64

respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 312.

Important: Before executing the `WFI` instruction, software must confirm that the EEPROM is not busy by checking to see that the `WORKING` bit in the **EEPROM Done Status (EEDONE)** register is clear.

To provide the lowest possible Deep-Sleep power consumption as well the ability to wake the processor from a peripheral without reconfiguring the peripheral for a change in clock, some of the communications modules have a Clock Control register at offset `0xFC8` in the module register space. The `CS` field in the Clock Control register allows the user to select the PIOSC as the clock source for the module's baud clock. When the microcontroller enters Deep-Sleep mode, the PIOSC becomes the source for the module clock as well, which allows the transmit and receive FIFOs to continue operation while the part is in Deep-Sleep. Figure 5-6 on page 222 shows how the clocks are selected.

Figure 5-6. Module Clock Selection

5.2.6.4 Hibernation Mode

In this mode, the power supplies are turned off to the main part of the microcontroller and only the Hibernation module's circuitry is active. An external wake event or RTC event is required to bring the microcontroller back to Run mode. The Cortex-M4F processor and peripherals outside of the Hibernation module see a normal "power on" sequence and the processor starts running code. Software can determine if the microcontroller has been restarted from Hibernation mode by inspecting the Hibernation module registers. For more information on the operation of Hibernation mode, see "Hibernation Module" on page 495.

5.3 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the `USERCC2` bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the `BYPASS` bit and clearing the `USESYS` bit in the **RCC** register, thereby configuring the microcontroller to run off a "raw" clock source

and allowing for the new PLL configuration to be validated before switching the system clock to the PLL.

2. Select the crystal value (*XTAL*) and oscillator source (*OSCSRC*), and clear the *PWRDN* bit in **RCC/RCC2**. Setting the *XTAL* field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the *PWRDN* bit powers and enables the PLL and its output.
3. Select the desired system divider (*SYSDIV*) in **RCC/RCC2** and set the *USESYS* bit in **RCC**. The *SYSDIV* field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the *PLLLRIS* bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the *BYPASS* bit in **RCC/RCC2**.

5.4 Register Map

Table 5-7 on page 223 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

Note: Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the “Internal Memory” on page 525.

Table 5-7. System Control Register Map

Offset	Name	Type	Reset	Description	See page
0x000	DID0	RO	-	Device Identification 0	229

5.5 Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000.

Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the microcontroller. Each microcontroller is uniquely identified by the combined values of the `CLASS` field in the **DID0** register and the `PARTNO` field in the **DID1** register.

Device Identification 0 (DID0)

Base 0x400F.E000

Offset 0x000

Type RO, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved	VER			reserved				CLASS							
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MAJOR								MINOR							
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description				
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
30:28	VER	RO	0x1	<p>DID0 Version</p> <p>This field defines the DID0 register format version. The version number is numeric. The value of the <code>VER</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Second version of the DID0 register format.</td> </tr> </tbody> </table>	Value	Description	0x1	Second version of the DID0 register format.
Value	Description							
0x1	Second version of the DID0 register format.							
27:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
23:16	CLASS	RO	0x05	<p>Device Class</p> <p>The <code>CLASS</code> field value identifies the internal design from which all mask sets are generated for all microcontrollers in a particular product line. The <code>CLASS</code> field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the <code>MAJOR</code> or <code>MINOR</code> fields require differentiation from prior microcontrollers. The value of the <code>CLASS</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x05</td> <td>Stellaris® Blizzard-class microcontrollers</td> </tr> </tbody> </table>	Value	Description	0x05	Stellaris® Blizzard-class microcontrollers
Value	Description							
0x05	Stellaris® Blizzard-class microcontrollers							

Bit/Field	Name	Type	Reset	Description								
15:8	MAJOR	RO	-	<p>Major Revision</p> <p>This field specifies the major revision number of the microcontroller. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Revision A (initial device)</td></tr><tr><td>0x1</td><td>Revision B (first base layer revision)</td></tr><tr><td>0x2</td><td>Revision C (second base layer revision)</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Revision A (initial device)	0x1	Revision B (first base layer revision)	0x2	Revision C (second base layer revision)
Value	Description											
0x0	Revision A (initial device)											
0x1	Revision B (first base layer revision)											
0x2	Revision C (second base layer revision)											
7:0	MINOR	RO	-	<p>Minor Revision</p> <p>This field specifies the minor revision number of the microcontroller. The minor revision reflects changes to the metal layers of the design. The MINOR field value is reset when the MAJOR field is changed. This field is numeric and is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Initial device, or a major revision update.</td></tr><tr><td>0x1</td><td>First metal layer change.</td></tr><tr><td>0x2</td><td>Second metal layer change.</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Initial device, or a major revision update.	0x1	First metal layer change.	0x2	Second metal layer change.
Value	Description											
0x0	Initial device, or a major revision update.											
0x1	First metal layer change.											
0x2	Second metal layer change.											

Register 2: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, pin count, and package type. Each microcontroller is uniquely identified by the combined values of the `CLASS` field in the `DID0` register and the `PARTNO` field in the `DID1` register.

Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset -

Bit/Field	Name	Type	Reset	Description						
31:28	VER	RO	0x1	<p>DID1 Version</p> <p>This field defines the DID1 register format version. The version number is numeric. The value of the <code>VER</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.</td> </tr> <tr> <td>0x1</td> <td>Second version of the DID1 register format.</td> </tr> </tbody> </table>	Value	Description	0x0	Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.	0x1	Second version of the DID1 register format.
Value	Description									
0x0	Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.									
0x1	Second version of the DID1 register format.									
27:24	FAM	RO	0x0	<p>Family</p> <p>This field provides the family identification of the device within the Stellaris product portfolio. The value is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Stellaris family of microcontrollers, that is, all devices with external part numbers starting with LM3S, LM4S, and LM4F.</td> </tr> </tbody> </table>	Value	Description	0x0	Stellaris family of microcontrollers, that is, all devices with external part numbers starting with LM3S, LM4S, and LM4F.		
Value	Description									
0x0	Stellaris family of microcontrollers, that is, all devices with external part numbers starting with LM3S, LM4S, and LM4F.									
23:16	PARTNO	RO	0x1	<p>Part Number</p> <p>This field provides the part number of the device within the family. The reset value shown indicates the LM4F120B2QR microcontroller.</p>						

Bit/Field	Name	Type	Reset	Description														
15:13	PINCOUNT	RO	0x3	<p>Package Pin Count</p> <p>This field specifies the number of pins on the device package. The value is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>28-pin package</td> </tr> <tr> <td>0x1</td> <td>48-pin package</td> </tr> <tr> <td>0x2</td> <td>100-pin package</td> </tr> <tr> <td>0x3</td> <td>64-pin package</td> </tr> <tr> <td>0x4</td> <td>144-pin package</td> </tr> <tr> <td>0x5</td> <td>157-pin package</td> </tr> </tbody> </table>	Value	Description	0x0	28-pin package	0x1	48-pin package	0x2	100-pin package	0x3	64-pin package	0x4	144-pin package	0x5	157-pin package
Value	Description																	
0x0	28-pin package																	
0x1	48-pin package																	
0x2	100-pin package																	
0x3	64-pin package																	
0x4	144-pin package																	
0x5	157-pin package																	
12:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.														
7:5	TEMP	RO	0x1	<p>Temperature Range</p> <p>This field specifies the temperature rating of the device. The value is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Commercial temperature range (0°C to 70°C)</td> </tr> <tr> <td>0x1</td> <td>Industrial temperature range (-40°C to 85°C)</td> </tr> <tr> <td>0x2</td> <td>Extended temperature range (-40°C to 105°C)</td> </tr> </tbody> </table>	Value	Description	0x0	Commercial temperature range (0°C to 70°C)	0x1	Industrial temperature range (-40°C to 85°C)	0x2	Extended temperature range (-40°C to 105°C)						
Value	Description																	
0x0	Commercial temperature range (0°C to 70°C)																	
0x1	Industrial temperature range (-40°C to 85°C)																	
0x2	Extended temperature range (-40°C to 105°C)																	
4:3	PKG	RO	0x1	<p>Package Type</p> <p>This field specifies the package type. The value is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SOIC package</td> </tr> <tr> <td>0x1</td> <td>LQFP package</td> </tr> <tr> <td>0x2</td> <td>BGA package</td> </tr> </tbody> </table>	Value	Description	0x0	SOIC package	0x1	LQFP package	0x2	BGA package						
Value	Description																	
0x0	SOIC package																	
0x1	LQFP package																	
0x2	BGA package

Register 3: Device Capabilities 0 (DC0), offset 0x008

This legacy register is predefined by the part and can be used to verify features.

Important: The **Flash Size (FSIZE)** and **SRAM Size (SSIZE)** registers should be used to determine this microcontroller's memory sizes. However, to support legacy software, the **DC0** register is available. A read of **DC0** correctly identifies legacy memory sizes but software must use **FSIZE** and **SSIZE** for memory sizes that are not listed below.

Device Capabilities 0 (DC0)

Register 4: Device Capabilities 1 (DC1), offset 0x010

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC0**, **SCGC0**, **DCGC0**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers cannot be set.

Important: The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. However, to support legacy software, the **DC1** register is available. A read of **DC1** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Likewise, the **ADC Peripheral Properties (ADCPP)** register should be used to determine the maximum ADC sample rate and whether the temperature sensor is present. However, to support legacy software, the **MAXADCnSPD** fields and the **TEMPSENS** bit are available. A read of **DC1** correctly identifies the maximum ADC sample rate for legacy rates and whether the temperature sensor is present.

See the RCC register for how to change the system clock divisor using the <i>SYSDIV</i> bit. Value Description 0x1 Specifies an 80-MHz CPU clock with a PLL divider of 2.5. 0x2 Specifies a 66-MHz CPU clock with a PLL divider of 3. 0x3 Specifies a 50-MHz CPU clock with a PLL divider of 4. 0x4 Specifies a 40-MHz CPU clock with a PLL divider of 5. 0x7 Specifies a 25-MHz clock with a PLL divider of 8. 0x9 Specifies a 20-MHz clock with a PLL divider of 10.
11:10	MAXADC1SPD	RO	0x3	Max ADC1 Speed This field indicates the maximum rate at which the ADC samples data. Value Description 0x3 1M samples/second 0x2 500K samples/second 0x1 250K samples/second 0x0 125K samples/second
9:8	MAXADC0SPD	RO	0x3	Max ADC0 Speed This field indicates the maximum rate at which the ADC samples data. Value Description 0x3 1M samples/second 0x2 500K samples/second 0x1 250K samples/second 0x0 125K samples/second
7	MPU	RO	0x1	MPU Present When set, indicates that the Cortex-M4F Memory Protection Unit (MPU) module is present. See the "Cortex-M4F Peripherals" chapter for details on the MPU.

Bit/Field	Name	Type	Reset	Description
6	HIB	RO	0x1	Hibernation Module Present When set, indicates that the Hibernation module is present.
5	TEMPSNS	RO	0x1	Temp Sensor Present When set, indicates that the on-chip temperature sensor is present.
4	PLL	RO	0x1	PLL Present When set, indicates that the on-chip Phase Locked Loop (PLL) is present.
3	WDT0	RO	0x1	Watchdog Timer 0 Present When set, indicates that watchdog timer 0 is present.
2	SWO	RO	0x1	SWO Trace Port Present When set, indicates that the Serial Wire Output (SWO) trace port is present.
1	SWD	RO	0x1	SWD Present When set, indicates that the Serial Wire Debugger (SWD) is present.
0	JTAG	RO	0x1	JTAG Present When set, indicates that the JTAG debugger interface is present.

Register 5: Device Capabilities 2 (DC2), offset 0x014

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC1**, **SCGC1**, **DCGC1**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers registers cannot be set.

Important: The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of **DC2** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Note that the **Analog Comparator Peripheral Present (PPACMP)** register identifies whether the analog comparator module is present. The **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are present in the module.

Register 8: Device Capabilities 5 (DC5), offset 0x020

This register is predefined by the part and can be used to verify PWM features. If any bit is clear in this register, the module is not present.

Important: The **PWM Peripheral Properties (PWMP)** register should be used to determine what pins and features are available on PWM modules. However, to support legacy software, this register is available. A read of this register correctly identifies if a legacy pin or feature is present. Software must use the **PWMP** register to determine if a pin or feature that is not supported by the **DCn** registers is present.

Register 11: Device Capabilities 8 (DC8), offset 0x02C

This register is predefined by the part and can be used to verify features.

Important: The **ADC Peripheral Properties (ADCPP)** register should be used to determine how many input channels are available on the ADC module. However, to support legacy software, the **DC8** register is available. A read of this register correctly identifies if legacy channels are present but software must use the **ADCPP** register to determine if a channel is present that is not supported by the **DCn** registers.

Register 13: Software Reset Control 0 (SRCR0), offset 0x040

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 1 (DC1)** register.

Important: The peripheral-specific Software Reset registers (such as **SRWD**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this legacy register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 14: Software Reset Control 1 (SRCR1), offset 0x044

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 2 (DC2)** register.

Important: The peripheral-specific Software Reset registers (such as **SRTIMER**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as **TIMER0**), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Note that the **Software Reset Analog Comparator (SRACMP)** register has only one bit to set the analog comparator module. Resetting the module resets all the blocks. If any of the **COMP_n** bits are set, the entire analog comparator module is reset. It is not possible to reset the blocks individually.

Register 16: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

Register 20: Run-Mode Clock Configuration (RCC), offset 0x060

The bits in this register configure the system clock and oscillators.

Important: Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

Register 21: GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced High-Performance Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 10-6 on page 655).

Important: Ports K-N and P-Q are only available on the AHB bus, and therefore the corresponding bits reset to 1. If one of these bits is cleared, the corresponding port is disabled. If any of these ports is in use, read-modify-write operations should be used to change the value of this register so that these ports remain enabled.

Register 22: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields, as shown in Table 5-8, when the `USERCC2` bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. Each **RCC2** field that supersedes an **RCC** field is located at the same LSB bit position; however, some **RCC2** fields are larger than the corresponding **RCC** field.

Table 5-8. RCC2 Fields that Override RCC Fields

RCC2 Field...	Overrides RCC Field
<code>SYSDIV2</code> , bits[28:23]	<code>SYSDIV</code> , bits[26:23]
<code>PWRDN2</code> , bit[13]	<code>PWRDN</code> , bit[13]
<code>BYPASS2</code> , bit[11]	<code>BYPASS</code> , bit[11]
<code>OSCSRC2</code> , bits[6:4]	<code>OSCSRC</code> , bits[5:4]

Important: Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

Register 23: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock verification circuit, what action to take when the MOSC fails, and whether or not a crystal is connected. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler or generates an interrupt.

2	NOXTAL	R/W	0	No Crystal Connected Value Description 1 This bit should be set when a crystal or external oscillator is not connected to the OSC0 and OSC1 inputs to reduce power consumption. 0 This bit should be cleared when a crystal or oscillator is connected to the OSC0 and OSC1 inputs, regardless of whether or not the MOSC is used or powered down.
1	MOSCIM	R/W	0	MOSC Failure Action Value Description 1 If the MOSC fails, an interrupt is generated as indicated by the MOPRIS bit in the RIS register.. 0 If the MOSC fails, a MOSC failure reset is generated and reboots to the NMI handler. Regardless of the action taken, if the MOSC fails, the oscillator source is switched to the PIOSC automatically.
0	CVAL	R/W	0	Clock Validation for MOSC Value Description 1 The MOSC monitor circuit is enabled. 0 The MOSC monitor circuit is disabled.

Register 24: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

Important: The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCWD**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Likewise, the **ADC Peripheral Configuration (ADCPC)** register should be used to configure the ADC sample rate. However, to support legacy software, the **MAXADCnSPD** fields are available. A write to these legacy fields also writes the corresponding field in the peripheral-specific register. If a field is changed by writing to this register, it can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support rates that are not available in this register. If software uses a peripheral-specific register to set the ADC rate, the write causes proper operation, but the value of that field is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 25: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

Important: The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCTIMER**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

17	ADC1	RO	0x0	ADC1 Clock Gating Control This bit controls the clock gating for ADC module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
16	ADC0	RO	0x0	ADC0 Clock Gating Control This bit controls the clock gating for ADC module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
15:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	HIB	RO	0x1	HIB Clock Gating Control This bit controls the clock gating for the Hibernation module. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
5:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
3	WDT0	RO	0x0	WDT0 Clock Gating Control This bit controls the clock gating for the Watchdog Timer module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 28: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Important: The peripheral-specific Sleep Mode Clock Gating Control registers (such as **SCGCTIMER**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

13	UDMA	RO	0x0	Micro-DMA Clock Gating Control This bit controls the clock gating for micro-DMA. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
12:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	GPIOJ	RO	0x0	Port J Clock Gating Control This bit controls the clock gating for Port J. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
7	GPIOH	RO	0x0	Port H Clock Gating Control This bit controls the clock gating for Port H. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
6	GPIOG	RO	0x0	Port G Clock Gating Control This bit controls the clock gating for Port G. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
5	GPIOF	RO	0x0	Port F Clock Gating Control This bit controls the clock gating for Port F. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
4	GPIOE	RO	0x0	Port E Clock Gating Control Port E Clock Gating Control. This bit controls the clock gating for Port E. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
3	GPIOD	RO	0x0	Port D Clock Gating Control Port D Clock Gating Control. This bit controls the clock gating for Port D. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
2	GPIOC	RO	0x0	Port C Clock Gating Control This bit controls the clock gating for Port C. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
1	GPIOB	RO	0x0	Port B Clock Gating Control This bit controls the clock gating for Port B. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
0	GPIOA	RO	0x0	Port A Clock Gating Control This bit controls the clock gating for Port A. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Register 30: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Important: The peripheral-specific Deep Sleep Mode Clock Gating Control registers (such as **DCGCWD**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Bit/Field	Name	Type	Reset	Description
0	UART0	RO	0x0	UART0 Clock Gating Control This bit controls the clock gating for UART module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Register 32: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Important: The peripheral-specific Deep Sleep Mode Clock Gating Control registers (such as **DCGCDMA**) should be used to reset specific peripherals. To support legacy software, this register is available. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the μ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

6:0	CT	RO	0x40	Calibration Trim Value This field contains the trim value from the last calibration operation. After factory calibration CT and DT are the same.

Register 37: PLL Frequency 0 (PLLREQ0), offset 0x160

This register always contains the current M value presented to the system PLL.

The PLL frequency can be calculated using the following equation:

$$\text{PLL frequency} = (\text{XTAL frequency} * \text{MDIV}) / ((Q + 1) * (N + 1))$$

where

$$\text{MDIV} = \text{MINT} + (\text{MFRAC} / 1024)$$

The Q and N values are shown in the **PLLREQ1** register. Table 23-10 on page 1173 shows the M, Q, and N values as well as the resulting PLL frequency for the various XTAL configurations.

				0 The PLL is unpowered or is not yet locked.

Register 40: Device Capabilities 9 (DC9), offset 0x190

This register is predefined by the part and can be used to verify ADC digital comparator features.

Important: The **ADC Peripheral Properties (ADCPP)** register should be used to determine how many digital comparators are available on the ADC module. However, to support legacy software, this register is available. A read of this register correctly identifies if legacy comparators are present. Software must use the **ADCPP** register to determine if a comparator that is not supported by the **DCn** registers is present.

Register 41: Non-Volatile Memory Information (NVMSTAT), offset 0x1A0

This register is predefined by the part and can be used to verify features.

Important: The **ROM Third-Party Software (ROMTPSW)** register should be used to determine the presence of third-party software in the on-chip ROM on this microcontroller. However, to support legacy software, a read of the **TPSW** bit in this register correctly identifies the presence of legacy third-party software. Software should use the **ROMTPSW** register for software that is not on legacy devices.

Register 58: Watchdog Timer Software Reset (SRWD), offset 0x500

The **SRWD** register provides software the capability to reset the available watchdog modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWD** register. While the **SRWD** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWD** bit.

There may be latency from the clearing of the **SRWD** bit to when the peripheral is ready for use. Software can check the corresponding **PRWD** bit to be sure.

Important: This register should be used to reset the watchdog modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 59: 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504

The **SRTIMER** register provides software the capability to reset the available 16/32-bit timer modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRTIMER** register. While the **SRTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRTIMER** bit.

There may be latency from the clearing of the **SRTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRTIMER** bit to be sure.

Important: This register should be used to reset the timer modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as Timer 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 60: General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508

The **SRGPIO** register provides software the capability to reset the available GPIO modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the GPIO modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRGPIO** register. While the **SRGPIO** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRGPIO** bit.

There may be latency from the clearing of the **SRGPIO** bit to when the peripheral is ready for use. Software can check the corresponding **PRGPIO** bit to be sure.

Important: This register should be used to reset the GPIO modules. To support legacy software, the **SRCR2** register is available. Setting a bit in the **SRCR2** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR2** register can be read back correctly when reading the **SRCR2** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 61: Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C

The **SRDMA** register provides software the capability to reset the available μ DMA module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the μ DMA module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRDMA** register. While the **SRDMA** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRDMA** bit.

There may be latency from the clearing of the **SRDMA** bit to when the peripheral is ready for use. Software can check the corresponding **PRDMA** bit to be sure.

Important: This register should be used to reset the μ DMA module. To support legacy software, the **SRCR2** register is available. Setting the **UDMA** bit in the **SRCR2** register also resets the μ DMA module. If the **UDMA** bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the μ DMA module, the write causes proper operation, but the value of the **UDMA** bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 62: Hibernation Software Reset (SRHIB), offset 0x514

The **SRHIB** register provides software the capability to reset the available Hibernation module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the Hibernation module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRHIB** register. While the **SRHIB** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRHIB** bit.

There may be latency from the clearing of the **SRHIB** bit to when the peripheral is ready for use. Software can check the corresponding **PRHIB** bit to be sure.

Important: This register should be used to reset the Hibernation module. To support legacy software, the **SRCR0** register is available. Setting the **HIB** bit in the **SRCR0** register also resets the Hibernation module. If the **HIB** bit is set by writing to the **SRCR0** register, it can be read back correctly when reading the **SRCR0** register. If software uses this register to reset the Hibernation module, the write causes proper operation, but the value of the **HIB** bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 63: Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518

The **SRUART** register provides software the capability to reset the available UART modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the UART modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUART** register. While the **SRUART** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUART** bit.

There may be latency from the clearing of the **SRUART** bit to when the peripheral is ready for use. Software can check the corresponding **PRUART** bit to be sure.

Important: This register should be used to reset the UART modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 64: Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C

The **SRSSI** register provides software the capability to reset the available SSI modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the SSI modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRSSI** register. While the **SRSSI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRSSI** bit.

There may be latency from the clearing of the **SRSSI** bit to when the peripheral is ready for use. Software can check the corresponding **PRSSI** bit to be sure.

Important: This register should be used to reset the SSI modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 65: Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520

The **SRI2C** register provides software the capability to reset the available I²C modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the I²C modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRI2C** register. While the **SRI2C** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRI2C** bit.

There may be latency from the clearing of the **SRI2C** bit to when the peripheral is ready for use. Software can check the corresponding **PRI2C** bit to be sure.

Important: This register should be used to reset the I²C modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as I2C0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 66: Universal Serial Bus Software Reset (SRUSB), offset 0x528

The **SRUSB** register provides software the capability to reset the available USB module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the USB module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUSB** register. While the **SRUSB** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUSB** bit.

There may be latency from the clearing of the **SRUSB** bit to when the peripheral is ready for use. Software can check the corresponding **PRUSB** bit to be sure.

Important: This register should be used to reset the USB module. To support legacy software, the **SRCR2** register is available. Setting the **USB0** bit in the **SRCR2** register also resets the USB module. If the **USB0** bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the USB module, the write causes proper operation, but the value of the **USB0** bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 69: Analog Comparator Software Reset (SRACMP), offset 0x53C

The **SRACMP** register provides software the capability to reset the available analog comparator module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the analog comparator module and has the same bit polarity as the corresponding **SRCRn** bits.

A block is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRACMP** register. While the **SRACMP** bit is 1, the module is held in reset.
2. Software completes the reset process by clearing the **SRACMP** bit.

There may be latency from the clearing of the **SRACMP** bit to when the module is ready for use. Software can check the corresponding **PRACMP** bit to be sure.

Important: This register should be used to reset the analog comparator module. To support legacy software, the **SRCR1** register is available. Setting any of the **COMPn** bits in the **SRCR0** register also resets the analog comparator module. If any of the **COMPn** bits are set by writing to the **SRCR1** register, it can be read back correctly when reading the **SRCR0** register. If software uses this register to reset the analog comparator module, the write causes proper operation, but the value of **R0** is not reflected by the **COMPn** bits in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 70: EEPROM Software Reset (SREEPROM), offset 0x558

The **SREEPROM** register provides software the capability to reset the available EEPROM module.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SREEPROM** register. While the **SREEPROM** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SREEPROM** bit.

There may be latency from the clearing of the **SREEPROM** bit to when the peripheral is ready for use. Software can check the corresponding **PREEEPROM** bit to be sure.

Register 71: 32/64-Bit Wide General-Purpose Timer Software Reset (SRWTIMER), offset 0x55C

The **SRWTIMER** register provides software the capability to reset the available 32/64-bit wide timer modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWTIMER** register. While the **SRWTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWTIMER** bit.

There may be latency from the clearing of the **SRWTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRWTIMER** bit to be sure.

Register 72: Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600

The **RCGCWD** register provides software the capability to enable and disable watchdog modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the watchdog modules. To support legacy software, the **RCGC0** register is available. A write to the **RCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC0** register can be read back correctly with a read of the **RCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 73: 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset 0x604

The **RCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the timer modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 74: General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO), offset 0x608

The **RCGCGPIO** register provides software the capability to enable and disable GPIO modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the GPIO modules. To support legacy software, the **RCGC2** register is available. A write to the **RCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC2** register can be read back correctly with a read of the **RCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **RCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 78: Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C

The **RCGCSSI** register provides software the capability to enable and disable the SSI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the SSI modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 80: Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628

The **RCGCUSB** register provides software the capability to enable and disable the USB module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the USB module. To support legacy software, the **RCGC2** register is available. A write to the **USB0** bit in the **RCGC2** register also writes the **R0** bit in this register. If the **USB0** bit is changed by writing to the **RCGC2** register, it can be read back correctly with a read of the **RCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the **USB0** bit in the **RCGC2** register does not reflect the value of the **R0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 81: Controller Area Network Run Mode Clock Gating Control (RCGCCAN), offset 0x634

The **RCGCCAN** register provides software the capability to enable and disable the CAN modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the CAN modules. To support legacy software, the RCGC0 register is available. A write to the RCGC0 register also writes the corresponding bit in this register. Any bits that are changed by writing to the RCGC0 register can be read back correctly with a read of the RCGC0 register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the RCGC0 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 83: Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C

The **RCGCACMP** register provides software the capability to enable and disable the analog comparator module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

Important: This register should be used to control the clocking for the analog comparator module. To support legacy software, the RCGC1 register is available. Setting any of the **COMPn** bits in the RCGC1 register also sets the **R0** bit in this register. If any of the **COMPn** bits are set by writing to the RCGC1 register, it can be read back correctly when reading the RCGC1 register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value **R0** is not reflected by the **COMPn** bits in the RCGC1 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 86: Watchdog Timer Sleep Mode Clock Gating Control (SCGCWD), offset 0x700

The **SCGCWD** register provides software the capability to enable and disable watchdog modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the watchdog modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 87: 16/32-Bit General-Purpose Timer Sleep Mode Clock Gating Control (SCGCTIMER), offset 0x704

The **SCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the timer modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 88: General-Purpose Input/Output Sleep Mode Clock Gating Control (SCGCGPIO), offset 0x708

The **SCGCGPIO** register provides software the capability to enable and disable GPIO modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the GPIO modules. To support legacy software, the **SCGC2** register is available. A write to the **SCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC2** register can be read back correctly with a read of the **SCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 89: Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C

The **SCGCDMA** register provides software the capability to enable and disable the μ DMA module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the μ DMA module. To support legacy software, the **SCGC2** register is available. A write to the **UDMA** bit in the **SCGC2** register also writes the **S0** bit in this register. If the **UDMA** bit is changed by writing to the **SCGC2** register, it can be read back correctly with a read of the **SCGC2** register. If software uses this register to control the clock for the μ DMA module, the write causes proper operation, but the **UDMA** bit in the **SCGC2** register does not reflect the value of the **S0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 90: Hibernation Sleep Mode Clock Gating Control (SCGCHIB), offset 0x714

The **SCGCHIB** register provides software the capability to enable and disable the Hibernation module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the Hibernation module. To support legacy software, the **SCGC0** register is available. A write to the **HIB** bit in the **SCGC0** register also writes the **S0** bit in this register. If the **HIB** bit is changed by writing to the **SCGC0** register, it can be read back correctly with a read of the **SCGC0** register. If software uses this register to control the clock for the Hibernation module, the write causes proper operation, but the **HIB** bit in the **SCGC0** register does not reflect the value of the **S0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 95: Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN), offset 0x734

The **SCGCCAN** register provides software the capability to enable and disable the CAN modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the CAN modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 96: Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738

The **SCGCADC** register provides software the capability to enable and disable the ADC modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the ADC modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 97: Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP), offset 0x73C

The **SCGCACMP** register provides software the capability to enable and disable the analog comparator module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

Important: This register should be used to control the clocking for the analog comparator module. To support legacy software, the **SCGC1** register is available. Setting any of the **COMPn** bits in the **SCGC1** register also sets the **S0** bit in this register. If any of the **COMPn** bits are set by writing to the **SCGC1** register, it can be read back correctly when reading the **SCGC1** register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value **S0** is not reflected by the **COMPn** bits in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 100: Watchdog Timer Deep-Sleep Mode Clock Gating Control (DCGCWD), offset 0x800

The **DCGCWD** register provides software the capability to enable and disable watchdog modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the watchdog modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 102: General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO), offset 0x808

The **DCGCGPIO** register provides software the capability to enable and disable GPIO modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the GPIO modules. To support legacy software, the **DCGC2** register is available. A write to the **DCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC2** register can be read back correctly with a read of the **DCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **DCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 103: Micro Direct Memory Access Deep-Sleep Mode Clock Gating Control (DCGCDMA), offset 0x80C

The **DCGCDMA** register provides software the capability to enable and disable the μ DMA module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the μ DMA module. To support legacy software, the **DCGC2** register is available. A write to the **UDMA** bit in the **DCGC2** register also writes the **D0** bit in this register. If the **UDMA** bit is changed by writing to the **DCGC2** register, it can be read back correctly with a read of the **DCGC2** register. If software uses this register to control the clock for the μ DMA module, the write causes proper operation, but the **UDMA** bit in the **DCGC2** register does not reflect the value of the **D0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

				1 Enable and provide a clock to the μ DMA module in deep-sleep mode.
				0 μ DMA module is disabled.

Register 104: Hibernation Deep-Sleep Mode Clock Gating Control (DCGCHIB), offset 0x814

The **DCGCHIB** register provides software the capability to enable and disable the Hibernation module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the Hibernation module. To support legacy software, the **DCGC0** register is available. A write to the **HIB** bit in the **DCGC0** register also writes the **D0** bit in this register. If the **HIB** bit is changed by writing to the **DCGC0** register, it can be read back correctly with a read of the **DCGC0** register. If software uses this register to control the clock for the Hibernation module, the write causes proper operation, but the **HIB** bit in the **DCGC0** register does not reflect the value of the **D0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 105: Universal Asynchronous Receiver/Transmitter Deep-Sleep Mode Clock Gating Control (DCGCUART), offset 0x818

The **DCGCUART** register provides software the capability to enable and disable the UART modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the UART modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Register 106: Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI), offset 0x81C

The **DCGCSSI** register provides software the capability to enable and disable the SSI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

Important: This register should be used to control the clocking for the SSI modules. To support legacy software, the **DCGC1** register is available. The **DCGCWTIMER** register provides software the capability to enable and disable 32/64-bit wide timer modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **DCGCn** bits.

Register 114: Watchdog Timer Power Control (PCWD), offset 0x900

The **PCWD** register controls the power provided to the watchdog modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Hardware should perform a peripheral reset using the **SRWD** register if the active mode changes and the corresponding bit in the **RCGCWD**, **SCGCWD**, or **DCGCWD** register is a 1 or the **P_n** bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The watchdog modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

Register 117: Micro Direct Memory Access Power Control (PCDMA), offset 0x90C

The **PCDMA** register controls the power provided to the μ DMA module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Hardware should perform a peripheral reset using the **SRDMA** register if the active mode changes and the corresponding bit in the **RCGCDMA**, **SCGCDMA**, or **DCGCDMA** register is a 1 or the P_n bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The μ DMA module does not currently have the ability to respond to the power down request. Setting the bit in this register has no effect on power consumption. This register is provided for future software compatibility.

0	P0	R/W	1	<p>μDMA Module Power Control</p> <p>The value of this bit does not have meaning unless the corresponding, active mode RCGCDMA, SCGCDMA or DCGCDMA bit is cleared.</p>

Value Description

- | | |
|---|---|
| 1 | The μ DMA module is powered, but does not receive a clock. In this case, the module is inactive.

This configuration provides the second-lowest power consumption of the module because it consumes only leakage current. |
| 0 | The μ DMA module is not powered and does not receive a clock. In this case, the module's state is not retained.

This configuration provides the lowest power consumption state of the module because it consumes no dynamic nor leakage current. |

Register 118: Hibernation Power Control (PCHIB), offset 0x914

The **PCHIB** register controls the power provided to the Hibernation module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Hardware should perform a peripheral reset using the **SRHIB** register if the active mode changes and the corresponding bit in the **RCGCHIB**, **SCGCHIB**, or **DCGCHIB** register is a 1 or the P_n bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The Hibernation module does not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

Register 119: Universal Asynchronous Receiver/Transmitter Power Control (PCUART), offset 0x918

The **PCUART** register controls the power provided to the UART modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Hardware should perform a peripheral reset using the **SRUART** register if the active mode changes and the corresponding bit in the **RCGCUART**, **SCGCUART**, or **DCGCUART** register is a 1 or the P_n bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The UART modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

1	P1	R/W	1	ADC Module 1 Power Control The value of this bit does not have meaning unless the corresponding, active mode RCGCADC , SCGCADC or DCGCADC bit is cleared.

Value Description

- | | |
|---|---|
| 1 | ADC module 1 is powered, but does not receive a clock. In this case, the module is inactive.

This configuration provides the second-lowest power consumption of the module because it consumes only leakage current. |
| 0 | ADC module 1 is not powered and does not receive a clock. In this case, the module's state is not retained.

This configuration provides the lowest power consumption state of the module because it consumes no dynamic nor leakage current. |

Bit/Field	Name	Type	Reset	Description
0	P0	R/W	1	<p>ADC Module 0 Power Control</p> <p>The value of this bit does not have meaning unless the corresponding, active mode RCGCADC, SCGCADC or DCGCADC bit is cleared.</p> <p>Value Description</p> <p>1 ADC module 0 is powered, but does not receive a clock. In this case, the module is inactive.</p> <p>This configuration provides the second-lowest power consumption of the module because it consumes only leakage current.</p> <p>0 ADC module 0 is not powered and does not receive a clock. In this case, the module's state is not retained.</p> <p>This configuration provides the lowest power consumption state of the module because it consumes no dynamic nor leakage current.</p>

Register 125: Analog Comparator Power Control (PCACMP), offset 0x93C

The **PCACMP** register controls the power provided to the analog comparator module. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Hardware should perform a peripheral reset using the **SRACMP** register if the active mode changes and the corresponding bit in the **RCGCACMP**, **SCGCACMP**, or **DCGCACMP** register is a 1 or the P_n bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The analog comparator module does not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

Register 126: EEPROM Power Control (PCEEPROM), offset 0x958

The **PCEEPROM** register controls the power provided to the EEPROM module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Hardware should perform a peripheral reset using the **SREEPROM** register if the active mode changes and the corresponding bit in the **RCGCEEPROM**, **SCGCEEPROM**, or **DCGCEEPROM** register is a 1 or the P_n bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The EEPROM module does not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

Register 127: 32/64-Bit Wide General-Purpose Timer Power Control (PCWTIMER), offset 0x95C

The **PCWTIMER** register controls the power provided to the 32/64-bit wide timer modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding modules state is not retained. Hardware should perform a peripheral reset using the **SRWTIMER** register if the active mode changes and the corresponding bit in the **RCGCWTIMER**, **SCGCWTIMER**, or **DCGCWTIMER** register is a 1 or the **P_n** bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

Note: The timer modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

Register 128: Watchdog Timer Peripheral Ready (PRWD), offset 0xA00

The **PRWD** register indicates whether the watchdog modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCWD** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCWD** bit is changed. A reset change is initiated if the corresponding **SRWD** bit is changed from 0 to 1.

The **PRWD** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

The **PRHIB** register indicates whether the Hibernation module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCHIB** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCHIB** bit is changed. A reset change is initiated if the corresponding **SRHIB** bit is changed from 0 to 1.

The **PRHIB** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

6 System Exception Module

This module is an AHB peripheral that handles system-level Cortex-M4 FPU exceptions. For functions with registers mapped into this aperture; if the function is not available on a device, then all writes to the associated registers are ignored and reads return zeros.

6.1 Functional Description

The System Exception module provides control and status of the system-level interrupts. All the interrupt events are ORed together before being sent to the interrupt controller, so the System Exception module can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **System Exception Masked Interrupt Status (SYSEXCMIIS)** register. The interrupt events that can trigger a controller-level interrupt are defined in the **System Exception Interrupt Mask (SYSEXCIM)** register by setting the corresponding interrupt mask bits. If interrupts are not used, the raw interrupt status is always visible via the **System Exception Raw Interrupt Status (SYSEXCRIS)** register. Interrupts are always cleared (for both the **SYSEXCMIIS** and **SYSEXCRIS** registers) by writing a 1 to the corresponding bit in the **System Exception Interrupt Clear (SYSEXCIC)** register.

6.2 Register Map

Table 6-1 on page 487 lists the System Exception module registers. The offset listed is a hexadecimal increment to the register's address, relative to the System Exception base address of 0x400F.9000.

Note: Spaces in the System Exception register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Table 6-1. System Exception Register Map

0x004	SYSEXCIM	R/W	0x0000.0000	System Exception Interrupt Mask	490
0x008	SYSEXCMIIS	RO	0x0000.0000	System Exception Masked Interrupt Status	492
0x00C	SYSEXCIC	W1C	0x0000.0000	System Exception Interrupt Clear	494

6.3 Register Descriptions

All addresses given are relative to the System Exception base address of 0x400F.9000.

Register 1: System Exception Raw Interrupt Status (SYSEXCRIS), offset 0x000

The **SYSEXCRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

System Exception Raw Interrupt Status (SYSEXCRIS)

Base 0x400F.9000
 Offset 0x000
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Register 2: System Exception Interrupt Mask (SYSEXCIM), offset 0x004

The **SYSEXCIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

System Exception Interrupt Mask (SYSEXCIM)

Base 0x400F.9000
 Offset 0x004
 Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:6	reserved	R/W	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	IXCIM	R/W	0	Inexact Exception Interrupt Mask Value Description 0 The IXCRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the ISCRIS bit in the SYSEXCIS register is set.
4	OFCIM	R/W	0	Overflow Exception Interrupt Mask Value Description 0 The OFCIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the OFCRIS bit in the SYSEXCIS register is set.
3	UFCIM	R/W	0	Underflow Exception Interrupt Mask Value Description 0 The UFCRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the UFCRIS bit in the SYSEXCIS register is set.

Bit/Field	Name	Type	Reset	Description
2	IOCIM	R/W	0	Invalid Operation Interrupt Mask Value Description 0 The <code>IOCRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>IOCRIS</code> bit in the <code>SYSEXCRI</code> S register is set.
1	DZCIM	R/W	0	Divide By 0 Exception Interrupt Mask Value Description 0 The <code>DZCRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>DZCRIS</code> bit in the <code>SYSEXCRI</code> S register is set.
0	IDCIM	R/W	0	Input Denormal Exception Interrupt Mask Value Description 0 The <code>IDCRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>IDCRIS</code> bit in the <code>SYSEXCRI</code> S register is set.

Register 3: System Exception Masked Interrupt Status (SYSEXCMIS), offset 0x008

The **SYSEXCMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

System Exception Masked Interrupt Status (SYSEXCMIS)

Base 0x400F.9000
 Offset 0x008
 Type RO, reset 0x0000.0000

5	IXCIC	W1C	0	Inexact Exception Interrupt Clear Writing a 1 to this bit clears the IXCRIS bit in the SYSEXCRCRIS register and the IXCMIS bit in the SYSEXCRCMIS register.
4	OFCIC	W1C	0	Overflow Exception Interrupt Clear Writing a 1 to this bit clears the OFCRIS bit in the SYSEXCRCRIS register and the OFCMIS bit in the SYSEXCRCMIS register.
3	UFCIC	W1C	0	Underflow Exception Interrupt Clear Writing a 1 to this bit clears the UFCRIS bit in the SYSEXCRCRIS register and the UFCMIS bit in the SYSEXCRCMIS register.
2	IOCIC	W1C	0	Invalid Operation Interrupt Clear Writing a 1 to this bit clears the IOCRIS bit in the SYSEXCRCRIS register and the IOCMIS bit in the SYSEXCRCMIS register.
1	DZCIC	W1C	0	Divide By 0 Exception Interrupt Clear Writing a 1 to this bit clears the DZCRIS bit in the SYSEXCRCRIS register and the DZCMIS bit in the SYSEXCRCMIS register.
0	IDCIC	W1C	0	Input Denormal Exception Interrupt Clear Writing a 1 to this bit clears the IDCRIS bit in the SYSEXCRCRIS register and the IDCMIS bit in the SYSEXCRCMIS register.

7 Hibernation Module

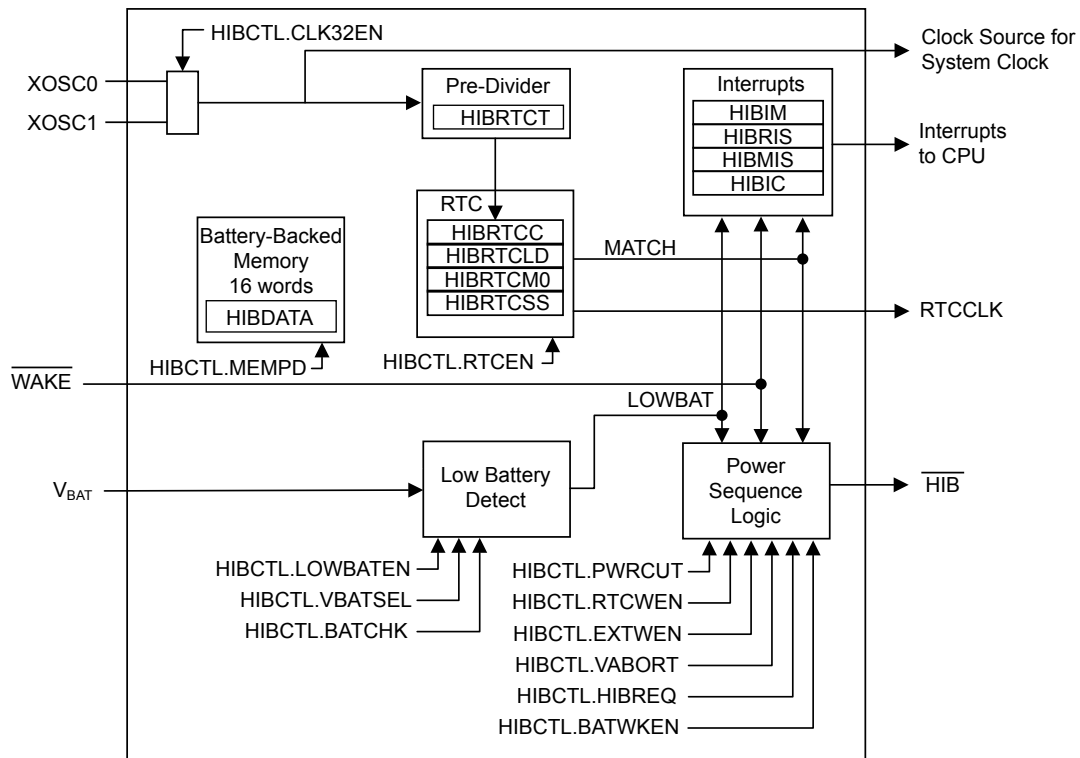

The Hibernation Module manages removal and restoration of power to provide a means for reducing power consumption. When the processor and peripherals are idle, power can be completely removed with only the Hibernation module remaining powered. Power can be restored based on an external signal or at a certain time using the built-in Real-Time Clock (RTC). The Hibernation module can be independently supplied from a battery or an auxiliary power supply.

The Hibernation module has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution
 - 32-bit RTC seconds match register and 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
 - RTC predivider trim for making fine adjustments to the clock rate
- Two mechanisms for power control
 - System power control using discrete external regulator
 - On-chip power control using internal switches under register control
- Dedicated pin for waking using an external signal
- RTC operational and hibernation memory valid as long as V_{BAT} is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from a 32.768-kHz external crystal or oscillator
- 16 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for RTC match, external wake, and low battery events

7.1 Block Diagram

Figure 7-1. Hibernation Module Block Diagram

7.2 Signal Description

The following table lists the external signals of the Hibernation module and describes the function of each.

The **RTCCLK** signal is an alternate function for a GPIO signal and defaults to be a GPIO signal at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the **RTCCLK** signal. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOPTL)** register (page 683) to assign the **RTCCLK** signal to the specified GPIO port pin. In addition, the **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the **RTCCLK** function. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

The remaining signals have a fixed pin assignment and function.

Table 7-1. Signals for Hibernate (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
GNDX	35	fixed	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should only be connected to the crystal load capacitors to improve oscillator immunity to system noise. When using an external oscillator, this pin should be connected to GND.

Table 7-1. Signals for Hibernate (64LQFP) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
$\overline{\text{HIB}}$	33	fixed	O	TTL	An output that indicates the processor is in Hibernate mode.
V _{BAT}	37	fixed	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
$\overline{\text{WAKE}}$	32	fixed	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
XOSC0	34	fixed	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
XOSC1	36	fixed	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

7.3 Functional Description

The Hibernation module provides two mechanisms for power control:

- The first mechanism controls the power to the microcontroller with a control signal ($\overline{\text{HIB}}$) that signals an external voltage regulator to turn on or off.
- The second mechanism uses internal switches to control power to the Cortex-M4F as well as to most analog and digital functions while retaining I/O pin power (VDD3ON mode).

The Hibernation module power source is determined dynamically. The supply voltage of the Hibernation module is the larger of the main voltage source (V_{DD}) or the battery/auxiliary voltage source (V_{BAT}). The Hibernation module also has an independent clock source to maintain a real-time clock (RTC) when the system clock is powered down. Hibernation mode can be entered through one of two ways:

- The user initiates hibernation by setting the `HIBREQ` bit in the **Hibernation Control (HIBCTL)** register
- Power is arbitrarily removed from V_{DD} while a valid V_{BAT} is applied

Once in hibernation, the module signals an external voltage regulator to turn the power back on when an external pin ($\overline{\text{WAKE}}$) is asserted or when the internal RTC reaches a certain value. The Hibernation module can also detect when the battery voltage is low and optionally prevent hibernation or wake from hibernation when this occurs.

When waking from hibernation, the $\overline{\text{HIB}}$ signal is deasserted. The return of V_{DD} causes a POR to be executed. The time from when the $\overline{\text{WAKE}}$ signal is asserted to when code begins execution is equal to the wake-up time ($t_{\text{WAKE_TO_HIB}}$) plus the power-on reset time (T_{POR}).

7.3.1 Register Access Timing

Because the Hibernation module has an independent clocking domain, hibernation registers must be written only with a timing gap between accesses. The delay time is $t_{\text{HIB_REG_ACCESS}}$, therefore

software must guarantee that this delay is inserted between back-to-back writes to Hibernation registers or between a write followed by a read. The `WC` interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed. Alternatively, software may make use of the `WRC` bit in the **Hibernation Control (HIBCTL)** register to ensure that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **HIBCTL** for `WRC=1` prior to accessing any hibernation register.

Back-to-back reads from Hibernation module registers have no timing restrictions. Reads are performed at the full peripheral clock rate.

7.3.2 Hibernation Clock Source

In systems where the Hibernation module is used to put the microcontroller into hibernation, the module must be clocked by an external source that is independent from the main system clock, even if the RTC feature is not used. An external oscillator or crystal is used for this purpose. To use a crystal, a 32.768-kHz crystal is connected to the `XOSC0` and `XOSC1` pins. Alternatively, a 32.768-kHz oscillator can be connected to the `XOSC0` pin, leaving `XOSC1` unconnected. Care must be taken that the voltage amplitude of the 32.768-kHz oscillator is less than V_{BAT} , otherwise, the Hibernation module may draw power from the oscillator and not V_{BAT} during hibernation. See Figure 7-2 on page 499 and Figure 7-3 on page 499.

The Hibernation clock source is enabled by setting the `CLK32EN` bit of the **HIBCTL** register. The `CLK32EN` bit must be set before accessing any other Hibernation module register. If a crystal is used for the clock source, the software must leave a delay of t_{HIBOSC_START} after writing to the `CLK32EN` bit and before any other accesses to the Hibernation module registers. The delay allows the crystal to power up and stabilize. If an oscillator is used for the clock source, no delay is needed. When using an external clock source, the `OSCBYP` bit in the **HIBCTL** register should be set. When using a crystal clock source, the `GNDX` pin should only be connected to the crystal load capacitors to improve oscillator immunity to system noise as shown in Figure 7-2 on page 499. When using an external clock source, the `GNDX` pin should be connected to `GND`.

Figure 7-2. Using a Crystal as the Hibernation Clock Source with a Single Battery Source

Note: X_1 = Crystal frequency is f_{XOSC_XTAL} .
 $C_{1,2}$ = Capacitor value derived from crystal vendor load capacitance specifications.
 R_{PU} = Pull-up resistor is 200 k Ω
 See "Hibernation Clock Source Specifications" on page 1174 for specific parameter values.

Figure 7-3. Using a Dedicated Oscillator as the Hibernation Clock Source with VDD3ON Mode

Note: R_{PU} = Pull-up resistor is 1 M Ω

7.3.3 System Implementation

Several different system configurations are possible when using the Hibernation module:

- Using a single battery source, where the battery provides both V_{DD} and V_{BAT} , as shown in Figure 7-2 on page 499.
- Using the VDD3ON mode, where V_{DD} continues to be powered in hibernation, allowing the GPIO pins to retain their states, as shown in Figure 7-3 on page 499. In this mode, V_{DDC} is powered off internally.

- Using separate sources for V_{DD} and V_{BAT} . In this mode, additional circuitry is required for system start-up without a battery or with a depleted battery, see the schematics for the EK-LM4F232 board for more information.
- Using a regulator to provide both V_{DD} and V_{BAT} with a switch enabled by \overline{HIB} to remove V_{DD} during hibernation as shown in Figure 7-4 on page 500.

Figure 7-4. Using a Regulator for Both V_{DD} and V_{BAT}

Adding external capacitance to the V_{BAT} supply reduces the accuracy of the low battery measurement and should be avoided if possible. The diagrams referenced in this section only show the connection to the Hibernation pins and not to the full system.

If the application does not require the use of the Hibernation module, refer to “Connections for Unused Signals” on page 1164. In this situation, the HIB bit in the **Run Mode Clock Gating Control Register 0 (RCGC0)** and the **Hibernation Run Mode Clock Gating Control (RCGCHIB)** registers must be cleared, disabling the system clock to the Hibernation module and Hibernation module registers are not accessible.

7.3.4 Battery Management

Important: System-level factors may affect the accuracy of the low battery detect circuit. The designer should consider battery type, discharge characteristics, and a test load during battery voltage measurements.

The Hibernation module can be independently powered by a battery or an auxiliary power source using the V_{BAT} pin. The module can monitor the voltage level of the battery and detect when the voltage drops below V_{LOWBAT} . The voltage threshold can be between 1.9 V and 2.5 V and is configured using the V_{BATSEL} field in the **HIBCTL** register. The module can also be configured so that it does not go into Hibernate mode if the battery voltage drops below this threshold. In addition, battery voltage is monitored while in hibernation, and the microcontroller can be configured to wake from hibernation if the battery voltage goes below the threshold using the $BATWKEN$ bit in the **HIBCTL** register.

The Hibernation module can be configured to detect a low battery condition by setting the $LOWBATEN$ bit of the **HIBCTL** register. In this configuration, the $LOWBAT$ bit of the **Hibernation Raw Interrupt Status (HIBRIS)** register is set when the battery level is low. If the $VABORT$ bit in the **HIBCTL** register

is also set, then the module is prevented from entering Hibernation mode when a low battery is detected. The module can also be configured to generate an interrupt for the low-battery condition (see “Interrupts and Status” on page 503).

Note that the Hibernation module draws power from whichever source (V_{BAT} or V_{DD}) has the higher voltage. Therefore, it is important to design the circuit to ensure that V_{DD} is higher than V_{BAT} under nominal conditions or else the Hibernation module draws power from the battery even when V_{DD} is available.

7.3.5 Real-Time Clock

The Hibernation module includes a real-time clock that consists of a 32-bit seconds counter and a 15-bit sub seconds counter. The clock signal from the 32.768-kHz Hibernation oscillator provides the clock source for the RTC. A buffered version of the 32.768-kHz signal is available on the `RTCCLK` output. The RTC counters are reset by the Hibernation module reset. The RTC 32-bit seconds counter can be set by the user using the **Hibernation RTC Load (HIBRTCLD)** register. When the 32-bit seconds counter is set, the 15-bit sub second counter is cleared. The RTC value can be read by first reading the **HIBRTCC** register, reading the `RTCSSC` field in the **Hibernation RTC Sub Seconds (HIBRTCSS)** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

The Hibernation module also includes a 32-bit match register and a 15-bit field (`RTCSSM`) in the **HIBRTCSS** register that are compared to the value of the RTC 32-bit counter and 15-bit sub seconds counter. When a match occurs, the processor can be programmed to wake from Hibernation mode and/or to generate an interrupt to the processor. The match interrupt generation takes priority over the interrupt clear. Therefore, writes to the `RTCALTO` bit in the **Hibernation Interrupt Clear (HIBIC)** register do not clear the bit if the RTC equals the match value. The match interrupt is cleared when the RTC is disabled using the `RTCEN` bit in the **HIBCTL** register.

The RTC counting rate can be adjusted to compensate for inaccuracies in the clock source by using the predivider trim register, **HIBRTCT**. This register has a nominal value of 0x7FFF, and is used for one second out of every 64 seconds, when bits [5:0] in the **HIBRTCC** register change from 0x00 to 0x01, to divide the input clock. This configuration allows the software to make fine corrections to the clock rate by adjusting the predivider trim register up or down from 0x7FFF. The predivider trim should be adjusted up from 0x7FFF in order to slow down the RTC rate and down from 0x7FFF in order to speed up the RTC rate.

Care must be taken when using trim values that are near to the sub seconds match value in the **HIBRTCSS** register. It is possible when using trim values above 0x7FFF to receive two match interrupts for the same counter value. In addition, it is possible when using trim values below 0x7FFF to miss a match interrupt.

In the case of a trim value above 0x7FFF, when the `RTCSSC` value in the **HIBRTCSS** register reaches 0x7FFF, the `RTCC` value increments from 0x0 to 0x1 while the `RTCSSC` value is decreased by the trim amount. The `RTCSSC` value is counted up again to 0x7FFF before rolling over to 0x0 to begin counting up again. If the match value is within this range, the match interrupt is triggered twice. For example, as shown in Table 7-2 on page 501, if the match interrupt was configured with `RTCM0=0x1` and `RTCSSM=0x7FFD`, two interrupts would be triggered.

Table 7-2. Counter Behavior with a TRIM Value of 0x8003

RTCC [6:0]	RTCSSC
0x00	0x7FFD
0x00	0x7FFE
0x00	0x7FFF

Table 7-2. Counter Behavior with a TRIM Value of 0x8003 (continued)

RTCC [6:0]	RTCSSC
0x01	0x7FFC
0x01	0x7FFD
0x01	0x7FFE
0x01	0x7FFF
0x01	0x0
0x01	0x1
-	-
0x01	0x7FFB
0x01	0x7FFC
0x01	0x7FFD
0x01	0x7FFE
0x01	0x7FFF
0x02	0x0

In the case of a trim value below 0x7FFF, the RTCSSC value is advanced from 0x7FFF to the trim value while the RTCC value is incremented from 0x0 to 0x1. If the match value is within that range, the match interrupt is not triggered. For example, as shown in Table 7-3 on page 502, if the match interrupt was configured with RTCM0=0x1 and RTCSSM=0x2, an interrupt would never be triggered.

Table 7-3. Counter Behavior with a TRIM Value of 0x7FFC

RTCC [6:0]	RTCSSC
0x00	0x7FFD
0x00	0x7FFE
0x00	0x7FFF
0x01	0x3
0x01	0x4
0x01	0x5

The RTC must be enabled with the RTCEN bit of the HIBCTL register. The RTC can be configured to generate interrupts by using the interrupt registers (see “Interrupts and Status” on page 503). As long as the RTC is enabled and a valid V_{BAT} is present, the RTC continues counting, regardless of whether V_{DD} is present or if the part is in hibernation.

7.3.6 Battery-Backed Memory

The Hibernation module contains 16 32-bit words of memory that are powered from the battery or auxiliary power supply and therefore retained during hibernation. The processor software can save state information in this memory prior to hibernation and recover the state upon waking. The battery-backed memory can be accessed through the HIBDATA registers. If both V_{DD} and V_{BAT} are removed, the contents of the HIBDATA registers are not retained.

7.3.7 Power Control Using $\overline{\text{HIB}}$

Important: The Hibernation Module requires special system implementation considerations when using $\overline{\text{HIB}}$ to control power, as it is intended to power-down all other sections of the

microcontroller. All system signals and power supplies that connect to the chip must be driven to 0 V_{DC} or powered down with the same regulator controlled by $\overline{\text{HIB}}$.

The Hibernation module controls power to the microcontroller through the use of the $\overline{\text{HIB}}$ pin which is intended to be connected to the enable signal of the external regulator(s) providing 3.3 V to the microcontroller and other circuits. When the $\overline{\text{HIB}}$ signal is asserted by the Hibernation module, the external regulator is turned off and no longer powers the microcontroller and any parts of the system that are powered by the regulator. The Hibernation module remains powered from the V_{BAT} supply (which could be a battery or an auxiliary power source) until a Wake event. Power to the microcontroller is restored by deasserting the $\overline{\text{HIB}}$ signal, which causes the external regulator to turn power back on to the chip.

7.3.8 Power Control Using VDD3ON Mode

The Hibernation module may also be configured to cut power to all internal modules. While in this state, all pins are held in the state they were in prior to entering hibernation. For example, inputs remain inputs; outputs driven high remain driven high, and so on. In the VDD3ON mode, the regulator should maintain 3.3 V power to the microcontroller during Hibernate. This power control mode is enabled by setting the VDD3ON bit in **HIBCTL**.

7.3.9 Initiating Hibernate

Hibernation mode is initiated when the HIBREQ bit of the **HIBCTL** register is set. If a wake up condition has not been configured using the PINWEN or RTCWEN bits in the **HIBCTL** register, the hibernation request is ignored. If a wake-up condition has not been configured but the CLK32EN bit is set, the MCU does go into hibernation when V_{DD} is arbitrarily removed; however, when V_{DD} is reapplied, the MCU executes a cold POR and the Hibernation module is reset. If a Flash memory write operation is in progress when the HIBREQ bit is set, an interlock feature holds off the transition into Hibernation mode until the write has completed. If V_{DD} is arbitrarily removed while a Flash memory write operation is in progress, the write operation must be retried after V_{DD} is reapplied. In addition, if the battery voltage is below the threshold voltage defined by the VBATSEL field in the **HIBCTL** register, the hibernation request is ignored.

The Hibernation module is configured to wake from the external $\overline{\text{WAKE}}$ pin by setting the PINWEN bit of the **HIBCTL** register. It is configured to wake from RTC match by setting the RTCWEN bit. Note that the $\overline{\text{WAKE}}$ pin uses the Hibernation module's internal power supply as the logic 1 reference.

Upon either external wake-up or RTC match, the Hibernation module delays coming out of hibernation until V_{DD} is above the minimum specified voltage, see Table 23-2 on page 1167.

When the Hibernation module wakes, the microcontroller performs a normal power-on reset. Software can detect that the power-on was due to a wake from hibernation by examining the raw interrupt status register (see "Interrupts and Status" on page 503) and by looking for state data in the battery-backed memory (see "Battery-Backed Memory" on page 502).

7.3.10 Interrupts and Status

The Hibernation module can generate interrupts when the following conditions occur:

- Assertion of $\overline{\text{WAKE}}$ pin
- RTC match
- Low battery detected

- Write complete/capable

All of the interrupts are ORed together before being sent to the interrupt controller, so the Hibernate module can only generate a single interrupt request to the controller at any given time. The software interrupt handler can service multiple interrupt events by reading the **Hibernation Masked Interrupt Status (HIBMIS)** register. Software can also read the status of the Hibernation module at any time by reading the **HIBRIS** register which shows all of the pending events. This register can be used after waking from hibernation to see if a wake condition was caused by one of the events above or by a power loss.

The events that can trigger an interrupt are configured by setting the appropriate bits in the **Hibernation Interrupt Mask (HIBIM)** register. Pending interrupts can be cleared by writing the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register.

7.4 Initialization and Configuration

The Hibernation module has several different configurations. The following sections show the recommended programming sequence for various scenarios. Because the Hibernation module runs at 32.768 kHz and is asynchronous to the rest of the microcontroller, which is run off the system clock, software must allow a delay of $t_{\text{HIB_REG_ACCESS}}$ after writes to registers (see “Register Access Timing” on page 497). The $\overline{\text{WC}}$ interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed.

7.4.1 Initialization

The Hibernation module comes out of reset with the system clock enabled to the module, but if the system clock to the module has been disabled, then it must be re-enabled, even if the RTC feature is not used. See page 378.

If a 32.768-kHz crystal is used as the Hibernation module clock source, perform the following steps:

1. Write 0x40 to the **HIBCTL** register at offset 0x10 to enable the oscillator input.
2. Wait until the $\overline{\text{WC}}$ interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

If a 32.678-kHz single-ended oscillator is used as the Hibernation module clock source, then perform the following steps:

1. Write 0x0001.0040 to the **HIBCTL** register at offset 0x10 to enable the oscillator input and bypass the on-chip oscillator.
2. Wait until the $\overline{\text{WC}}$ interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

The above steps are only necessary when the entire system is initialized for the first time. If the microcontroller has been in hibernation, then the Hibernation module has already been powered up and the above steps are not necessary. The software can detect that the Hibernation module and clock are already powered by examining the **CLK32EN** bit of the **HIBCTL** register.

Table 7-4 on page 505 illustrates how the clocks function with various bit setting both in normal operation and in hibernation.

Table 7-4. Hibernation Module Clock Operation

CLK32EN	PINWEN	RTCWEN	RTCEN	Result Normal Operation	Result Hibernation
0	X	X	X	Hibernation module disabled	Hibernation module disabled
1	0	0	1	RTC match capability enabled.	No hibernation
1	0	1	1	Module clocked	RTC match for wake-up event
1	1	0	0	Module clocked	Clock is powered down during hibernation and powered up again on external wake-up event.
1	1	0	1	Module clocked	Clock is powered up during hibernation for RTC. Wake up on external event.
1	1	1	1	Module clocked	RTC match or external wake-up event, whichever occurs first.

7.4.2 RTC Match Functionality (No Hibernation)

Use the following steps to implement the RTC match functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
4. Set the required RTC match interrupt mask in the **RTCALTO** in the **HIBIM** register at offset 0x014.
5. Write 0x0000.0041 to the **HIBCTL** register at offset 0x010 to enable the RTC to begin counting.

7.4.3 RTC Match/Wake-Up from Hibernation

Use the following steps to implement the RTC match and wake-up functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.
4. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match Wake-Up and start the hibernation sequence by writing 0x0000.004B to the **HIBCTL** register at offset 0x010.

7.4.4 External Wake-Up from Hibernation

Use the following steps to implement the Hibernation module with the external $\overline{\text{WAKE}}$ pin as the wake-up source for the microcontroller:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.

2. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x06F.
3. Enable the external wake and start the hibernation sequence by writing 0x0000.0052 to the **HIBCTL** register at offset 0x010.

Note that in this mode, if the RTC is disabled, then the Hibernation clock source is powered down during Hibernation mode and is powered up again on the external wake event to save power during hibernation. If the RTC is enabled before hibernation, it continues to operate during hibernation.

7.4.5 RTC or External Wake-Up from Hibernation

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.
4. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match/External Wake-Up and start the hibernation sequence by writing 0x0000.005B to the **HIBCTL** register at offset 0x010.

7.5 Register Map

Table 7-5 on page 506 lists the Hibernation registers. All addresses given are relative to the Hibernation Module base address at 0x400F.C000. Note that the system clock to the Hibernation module must be enabled before the registers can be programmed (see page 378). There must be a delay of 3 system clocks after the Hibernation module clock is enabled before any Hibernation module registers are accessed. In addition, the **CLK32EN** bit in the **HIBCTL** register must be set before accessing any other Hibernation module register.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

Important: The Hibernation module registers are reset under two conditions:

1. A system reset when the **RTCEN** and the **PINWEN** bits in the **HIBCTL** register are both cleared.
2. A cold POR, when both the **V_{DD}** and **V_{BAT}** supplies are removed.

Any other reset condition is ignored by the Hibernation module.

7.6 Register Descriptions

The remainder of this section lists and describes the Hibernation module registers, in numerical order by address offset.

Register 1: Hibernation RTC Counter (HIBRTCC), offset 0x000

This register is the current 32-bit value of the RTC counter.

The RTC counter consists of a 32-bit seconds counter and a 15-bit sub seconds counter. The RTC counters are reset by the Hibernation module reset. The RTC 32-bit seconds counter can be set by the user using the **HIBRTCLD** register. When the 32-bit seconds counter is set, the 15-bit sub second counter is cleared.

The RTC value can be read by first reading the **HIBRTCC** register, reading the **RTCCSSC** field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

Hibernation RTC Counter (HIBRTCC)

Base 0x400F.C000
 Offset 0x000
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RTCC	RO	0x0000.0000	RTC Counter A read returns the 32-bit counter value, which represents the seconds elapsed since the RTC was enabled. This register is read-only. To change the value, use the HIBRTCLD register.

Register 2: Hibernation RTC Match 0 (HIBRTCM0), offset 0x004

This register is the 32-bit seconds match register for the RTC counter. The 15-bit sub second match value is stored in the reading the `RTCSSC` field in the **HIBRTCSS** register and can be used in conjunction with this register for a more precise time match.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

Hibernation RTC Match 0 (HIBRTCM0)

Base 0x400F.C000

Offset 0x004

Type R/W, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RTCM0															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RTCM0															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit/Field	Name	Type	Reset	Description
31:0	RTCM0	R/W	0xFFFF.FFFF	RTC Match 0 A write loads the value into the RTC match register. A read returns the current match value.

Register 3: Hibernation RTC Load (HIBRTCLD), offset 0x00C

This register is used to load a 32-bit value loaded into the RTC counter. The load occurs immediately upon this register being written. When this register is written, the 15-bit sub seconds counter is also cleared.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the `HIBCTL` register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

Hibernation RTC Load (HIBRTCLD)

Base 0x400F.C000
 Offset 0x00C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RTCLD	R/W	0x0000.0000	RTC Load A write loads the current value into the RTC counter (RTCC). A read returns the 32-bit load value.

Register 4: Hibernation Control (HIBCTL), offset 0x010

This register is the control register for the Hibernation module. This register must be written last before a hibernate event is issued. Writes to other registers after the HIBREQ bit is set are not guaranteed to complete before hibernation is entered.

Hibernation Control (HIBCTL)

Base 0x400F.C000

Offset 0x010

Type R/W, reset 0x8000.0000

Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31	WRC	RO	1	<p>Write Complete/Capable</p> <p>Value Description</p> <p>0 The interface is processing a prior write and is busy. Any write operation that is attempted while WRC is 0 results in undetermined behavior.</p> <p>1 The interface is ready to accept a write.</p> <p>Software must poll this bit between write requests and defer writes until WRC=1 to ensure proper operation.</p> <p>The bit name WRC means "Write Complete," which is the normal use of the bit (between write accesses). However, because the bit is set out-of-reset, the name can also mean "Write Capable" which simply indicates that the interface may be written to by software. This difference may be exploited by software at reset time to detect which method of programming is appropriate: 0 = software delay loops required; 1 = WRC paced available.</p>
30:19	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
18	OSCHYS	R/W	0	<p>32.768-kHz Oscillator Hysteresis Control</p> <p>This bit is used to prevent self oscillations when the Hibernation oscillator is powered down or does not have a crystal attached. For lowest power states, this should be set.</p> <p>Value Description</p> <p>1 Hysteresis is enabled.</p> <p>0 Hysteresis is disabled.</p>

Bit/Field	Name	Type	Reset	Description
17	OSCDRV	R/W	0	<p>Oscillator Drive Capability</p> <p>This bit is used to compensate for larger or smaller filtering capacitors.</p> <p>Note: This bit is not meant to be changed once the Hibernation oscillator has started. Oscillator stability is not guaranteed if the user changes this value after the the oscillator is running.</p> <p>Value Description</p> <p>1 High drive strength is enabled, 24 pF.</p> <p>0 Low drive strength is enabled, 12 pF.</p>
16	OSCBYP	R/W	0	<p>Oscillator Bypass</p> <p>Value Description</p> <p>1 The internal 32.768-kHz Hibernation oscillator is disabled and powered down. This bit should be set when using a single-ended oscillator attached to XOSC0.</p> <p>0 The internal 32.768-kHz Hibernation oscillator is enabled. This bit should be cleared when using an external 32.768-kHz crystal.</p>
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:13	VBATSEL	R/W	0x1	<p>Select for Low-Battery Comparator</p> <p>This field selects the battery level that is used when checking the battery status. If the battery voltage is below the specified level, the LOWBAT interrupt bit in the HIBRIS register is set.</p> <p>Value Description</p> <p>0x0 1.9 Volts</p> <p>0x1 2.1 Volts (default)</p> <p>0x2 2.3 Volts</p> <p>0x3 2.5 Volts</p>
12:11	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	BATCHK	R/W	0	<p>Check Battery Status</p> <p>Value Description</p> <p>1 When read, indicates the low battery comparator cycle has not completed.</p> <p>Setting this bit initiates a low battery comparator cycle. If the battery voltage is below the level specified by VBATSEL field, the LOWBAT interrupt bit in the HIBRIS register is set. A hibernation request is held off if a battery check is in progress.</p> <p>0 When read, indicates that the low batter comparator cycle is not active.</p> <p>Writing a 0 has no effect.</p>

Bit/Field	Name	Type	Reset	Description
9	BATWKEN	R/W	0	<p>Wake on Low Battery</p> <p>Value Description</p> <p>1 When this bit is set, the battery voltage level is checked every 512 seconds while in hibernation. If the voltage is below the level specified by <code>VBATSEL</code> field, the microcontroller wakes from hibernation and the <code>LOWBAT</code> interrupt bit in the <code>HIBRIS</code> register is set.</p> <p>0 The battery voltage level is not automatically checked. Low battery voltage does not cause the microcontroller to wake from hibernation.</p>
8	VDD3ON	R/W	0	<p>VDD Powered</p> <p>Value Description</p> <p>1 The internal switches control the power to the on-chip modules (<code>VDD3ON</code> mode).</p> <p>0 The internal switches are not used. The <code>HIB</code> signal should be used to control an external switch or regulator.</p> <p>Note that regardless of the status of the <code>VDD3ON</code> bit, the <code>HIB</code> signal is asserted during Hibernate mode. Thus, when <code>VDD3ON</code> is set, the <code>HIB</code> signal should not be connected to the 3.3V regulator, and the 3.3V power source should remain connected. When this bit is set while in hibernation, all pins are held in the state they were in prior to entering hibernation. For example, inputs remain inputs; outputs driven high remain driven high, and so on.</p>
7	VABORT	R/W	0	<p>Power Cut Abort Enable</p> <p>Value Description</p> <p>1 When this bit is set, the battery voltage level is checked before entering hibernation. If <code>V_{BAT}</code> is less than the voltage specified by <code>VBATSEL</code>, the microcontroller does not go into hibernation.</p> <p>0 The microcontroller goes into hibernation regardless of the voltage level of the battery.</p>
6	CLK32EN	R/W	0	<p>Clocking Enable</p> <p>This bit must be enabled to use the Hibernation module.</p> <p>Value Description</p> <p>1 The Hibernation module clock source is enabled.</p> <p>0 The Hibernation module clock source is disabled.</p>

Bit/Field	Name	Type	Reset	Description						
5	LOWBATEN	R/W	0	<p>Low Battery Monitoring Enable</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Low battery voltage detection is enabled. Value	Description									
1	The Hibernation module RTC is enabled.									
0	The Hibernation module RTC is disabled.									

Register 5: Hibernation Interrupt Mask (HIBIM), offset 0x014

This register is the interrupt mask register for the Hibernation module interrupt sources. Each bit in this register masks the corresponding bit in the **Hibernation Raw Interrupt Status (HIBRIS)** register. If a bit is unmasked, the interrupt is sent to the interrupt controller. If the bit is masked, the interrupt is not sent to the interrupt controller. If the **WC** bit is set before the **CLK32EN** has been set, the mask value is not preserved over a hibernate cycle unless the bit is written a second time.

Hibernation Interrupt Mask (HIBIM)

0	RTCALTO	R/W	0	RTC Alert 0 Interrupt Mask
				Value Description
			1	An interrupt is sent to the interrupt controller when the RTCALTO bit in the HIBRIS register is set.
			0	The RTCALTO interrupt is suppressed and not sent to the interrupt controller.

Register 6: Hibernation Raw Interrupt Status (HIBRIS), offset 0x018

This register is the raw interrupt status for the Hibernation module interrupt sources. Each bit can be masked by clearing the corresponding bit in the **HIBIM** register. When a bit is masked, the interrupt is not sent to the interrupt controller. Bits in this register are cleared by writing a 1 to the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register or by entering hibernation.

31:5	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	WC	RO	0	Write Complete/Capable Raw Interrupt Status Value Description 1 The WRC bit in the HIBCTL has been set. 0 The WRC bit in the HIBCTL has not been set. This bit is cleared by writing a 1 to the WC bit in the HIBIC register.
3	EXTW	RO	0	External Wake-Up Raw Interrupt Status Value Description 1 The WAKE pin has been asserted. 0 The WAKE pin has not been asserted. This bit is cleared by writing a 1 to the EXTW bit in the HIBIC register.
2	LOWBAT	RO	0	Low Battery Voltage Raw Interrupt Status Value Description 1 The battery voltage dropped below V_{LOWBAT} . 0 The battery voltage has not dropped below V_{LOWBAT} . This bit is cleared by writing a 1 to the LOWBAT bit in the HIBIC register.
1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	RTCALTO	RO	0	RTC Alert 0 Raw Interrupt Status
				Value Description
			1	The value of the HIBRTCC register matches the value in the HIBRTCM0 register and the value of the RTCSSC field matches the RTCSSM field in the HIBRTCSS register.
			0	No match
				This bit is cleared by writing a 1 to the RTCALTO bit in the HIBIC register.

Register 7: Hibernation Masked Interrupt Status (HIBMIS), offset 0x01C

This register is the masked interrupt status for the Hibernation module interrupt sources. Bits in this register are the AND of the corresponding bits in the **HIBRIS** and **HIBIM** registers. When both corresponding bits are set, the bit in this register is set, and the interrupt is sent to the interrupt controller.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	WC	R/W1C	0	Write Complete/Capable Masked Interrupt Clear Writing a 1 to this bit clears the WC bit in the HIBRIS and HIBMIS registers. Reads return an indeterminate value.
3	EXTW	R/W1C	0	External Wake-Up Masked Interrupt Clear Writing a 1 to this bit clears the EXTW bit in the HIBRIS and HIBMIS registers. Reads return an indeterminate value.
2	LOWBAT	R/W1C	0	Low Battery Voltage Masked Interrupt Clear Writing a 1 to this bit clears the LOWBAT bit in the HIBRIS and HIBMIS registers. Reads return an indeterminate value.
1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RTCALTO	R/W1C	0	RTC Alert0 Masked Interrupt Clear Writing a 1 to this bit clears the RTCALTO bit in the HIBRIS and HIBMIS registers. Reads return an indeterminate value.

Note: The timer interrupt source cannot be cleared if the RTC value and the **HIBRTCM0** register / **RTCSS** field values are equal. The match interrupt takes priority over the interrupt clear.

Register 9: Hibernation RTC Trim (HIBRTCT), offset 0x024

This register contains the value that is used to trim the RTC clock predivider. It represents the computed underflow value that is used during the trim cycle. It is represented as $0x7FFF \pm N$ clock cycles, where N is the number of clock cycles to add or subtract every 63 seconds.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the `HIBCTL` register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

Hibernation RTC Trim (HIBRTCT)

Base 0x400F.C000
 Offset 0x024
 Type R/W, reset 0x0000.7FFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TRIM	R/W	0x7FFF	RTC Trim Value This value is loaded into the RTC predivider every 64 seconds. It is used to adjust the RTC rate to account for drift and inaccuracy in the clock source. Compensation can be adjusted by software by moving the default value of 0x7FFF up or down. Moving the value up slows down the RTC and moving the value down speeds up the RTC.

Register 10: Hibernation RTC Sub Seconds (HIBRTCSS), offset 0x028

This register contains the RTC sub seconds counter and match values. The RTC value can be read by first reading the **HIBRTCC** register, reading the **RTCSSC** field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30:16	RTCSSM	R/W	0x7FFF	RTC Sub Seconds Match A write loads the value into the RTC sub seconds match register in 1/32,768 of a second increments. A read returns the current 1/32,768 seconds match value.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:0	RTCSSC	RO	0x0000	RTC Sub Seconds Count A read returns the sub second RTC count in 1/32,768 seconds.

Register 11: Hibernation Data (HIBDATA), offset 0x030-0x06F

This address space is implemented as a 16x32-bit memory (64 bytes). It can be loaded by the system processor in order to store state information and does not lose power during a power cut operation as long as a battery is present. The MEMPD bit in the HIBCTL register must be clear in order to be able to access the HIBDATA registers.

Note: The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the WRC bit in the HIBCTL register to ensure that the required timing gap has elapsed. If the WRC bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 497.

31:0	RTD	R/W	-	Hibernation Module NV Data

8 Internal Memory

The LM4F120B2QR microcontroller comes with 12 KB of bit-banded SRAM, internal ROM, 32 KB of Flash memory, and 2KB of EEPROM. The Flash memory controller provides a user-friendly interface, making Flash memory programming a simple task. Flash memory protection can be applied to the Flash memory on a 2-KB block basis. The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme. A password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

8.1 Block Diagram

Figure 8-1 on page 525 illustrates the internal SRAM, ROM, and Flash memory blocks and control logic. The dashed boxes in the figure indicate registers residing in the System Control module.

Figure 8-1. Internal Memory Block Diagram

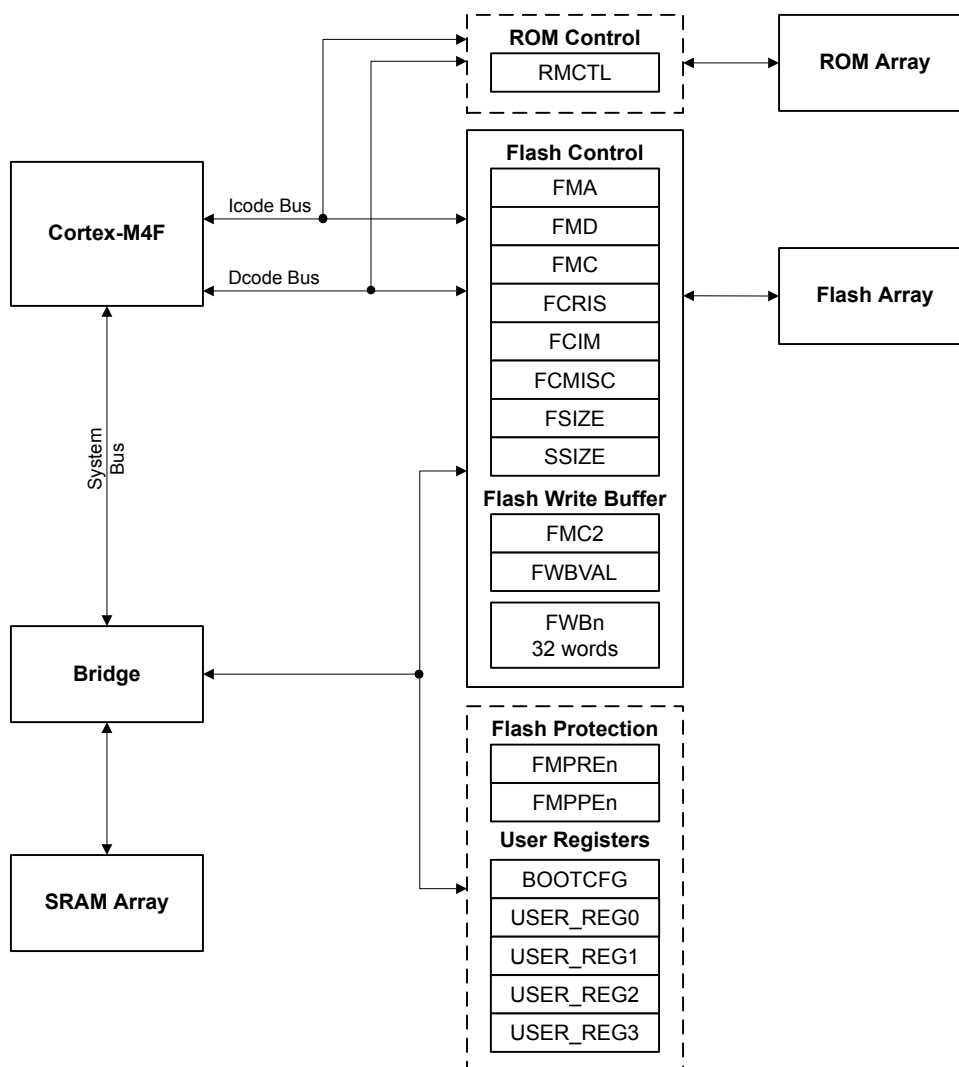

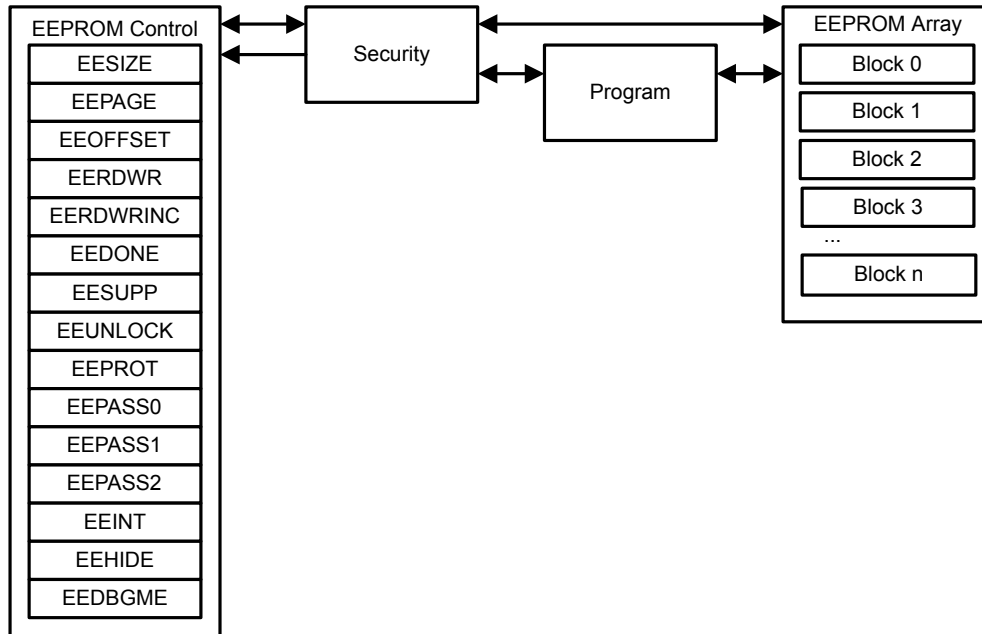

Figure 8-2 on page 526 illustrates the internal EEPROM block and control logic. The EEPROM block is connected to the AHB bus.

Figure 8-2. EEPROM Block Diagram

8.2 Functional Description

This section describes the functionality of the SRAM, ROM, Flash, and EEPROM memories.

Note: The μ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the μ DMA controller.

8.2.1 SRAM

The internal SRAM of the Stellaris[®] devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time-consuming read-modify-write (RMW) operations, ARM provides bit-banding technology in the processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation. The bit-band base is located at address 0x2200.0000.

The bit-band alias is calculated by using the formula:

$$\text{bit-band alias} = \text{bit-band base} + (\text{byte offset} * 32) + (\text{bit number} * 4)$$

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

$$0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C$$

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, see "Bit-Banding" on page 90.

Note: The SRAM is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned such that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank incurs a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

8.2.2 ROM

The internal ROM of the Stellaris device is located at address 0x0100.0000 of the device memory map. Detailed information on the ROM contents can be found in the *Stellaris® ROM User's Guide*.

The ROM contains the following components:

- Stellaris Boot Loader and vector table
- Stellaris Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error detection functionality

The boot loader is used as an initial program loader (when the Flash memory is empty) as well as an application-initiated firmware upgrade mechanism (by calling back to the boot loader). The Peripheral Driver Library APIs in ROM can be called by applications, reducing Flash memory requirements and freeing the Flash memory to be used for other purposes (such as additional features in the application). Advance Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government and Cyclic Redundancy Check (CRC) is a technique to validate a span of data has the same contents as when previously checked.

8.2.2.1 Boot Loader Overview

The Stellaris Boot Loader is used to download code to the Flash memory of a device without the use of a debug interface. When the core is reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal in Ports A-H as configured in the **Boot Configuration (BOOTCFG)** register.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

The boot loader uses a simple packet interface to provide synchronous communication with the device. The speed of the boot loader is determined by the internal oscillator (PIOSC) frequency as it does not enable the PLL. The following serial interfaces can be used:

- UART0
- SSIO
- I²C0
- USB

For simplicity, both the data format and communication protocol are identical for all serial interfaces.

Note: The Flash-memory-resident version of the Boot Loader also supports CAN.

See the *Stellaris® Boot Loader User's Guide* for information on the boot loader software.

8.2.2.2 Stellaris Peripheral Driver Library

The Stellaris Peripheral Driver Library contains a file called `driverlib/rom.h` that assists with calling the peripheral driver library functions in the ROM. The detailed description of each function is available in the *Stellaris® ROM User's Guide*. See the "Using the ROM" chapter of the *Stellaris® Peripheral Driver Library User's Guide* for more details on calling the ROM functions and using `driverlib/rom.h`.

A table at the beginning of the ROM points to the entry points for the APIs that are provided in the ROM. Accessing the API through these tables provides scalability; while the API locations may change in future versions of the ROM, the API tables will not. The tables are split into two levels; the main table contains one pointer per peripheral which points to a secondary table that contains one pointer per API that is associated with that peripheral. The main table is located at 0x0100.0010, right after the Cortex-M4F vector table in the ROM.

DriverLib functions are described in detail in the *Stellaris® Peripheral Driver Library User's Guide*.

Additional APIs are available for graphics and USB functions, but are not preloaded into ROM. The Stellaris Graphics Library provides a set of graphics primitives and a widget set for creating graphical user interfaces on Stellaris microcontroller-based boards that have a graphical display (for more information, see the *Stellaris® Graphics Library User's Guide*). The Stellaris USB Library is a set of data types and functions for creating USB Device, Host or On-The-Go (OTG) applications on Stellaris microcontroller-based boards (for more information, see the *Stellaris® USB Library User's Guide*).

8.2.2.3 Advanced Encryption Standard (AES) Cryptography Tables

AES is a strong encryption method with reasonable performance and size. AES is fast in both hardware and software, is fairly easy to implement, and requires little memory. AES is ideal for applications that can use pre-arranged keys, such as setup during manufacturing or configuration. Four data tables used by the XySSL AES implementation are provided in the ROM. The first is the forward S-box substitution table, the second is the reverse S-box substitution table, the third is the forward polynomial table, and the final is the reverse polynomial table. See the *Stellaris® ROM User's Guide* for more information on AES.

8.2.2.4 Cyclic Redundancy Check (CRC) Error Detection

The CRC technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily. See the *Stellaris® ROM User's Guide* for more information on CRC.

8.2.3 Flash Memory

At system clock speeds of 40 MHz and below, the Flash memory is read in a single cycle. The Flash memory is organized as a set of 1-KB blocks that can be individually erased. An individual 32-bit word can be programmed to change bits from 1 to 0. In addition, a write buffer provides the ability to program 32 continuous words in Flash memory in half the time of programming the words individually. Erasing a block causes the entire contents of the block to be reset to all 1s. The 1-KB blocks are paired into sets of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

8.2.3.1 Prefetch Buffer

The Flash memory controller has a prefetch buffer that is automatically used when the CPU frequency is greater than 40 MHz. In this mode, the Flash memory operates at half of the system clock. The prefetch buffer fetches two 32-bit words per clock allowing instructions to be fetched with no wait states while code is executing linearly. The fetch buffer includes a branch speculation mechanism that recognizes a branch and avoids extra wait states by not reading the next word pair. Also, short loop branches often stay in the buffer. As a result, some branches can be executed with no wait states. Other branches incur a single wait state.

8.2.3.2 Flash Memory Protection

The user is provided two forms of Flash memory protection per 2-KB Flash memory block in one pair of 32-bit wide registers. The policy for each protection form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn)**: If a bit is set, the corresponding block may be programmed (written) or erased. If a bit is cleared, the corresponding block may not be changed.
- **Flash Memory Protection Read Enable (FMPREn)**: If a bit is set, the corresponding block may be executed or read by software or debuggers. If a bit is cleared, the corresponding block may only be executed, and contents of the memory block are prohibited from being read as data.

The policies may be combined as shown in Table 8-1 on page 529.

Table 8-1. Flash Memory Protection Policy Combinations

FMPPEn	FMPREn	Protection
0	0	Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0	1	Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

A Flash memory access that attempts to read a read-protected block (**FMPREn** bit is set) is prohibited and generates a bus fault. A Flash memory access that attempts to program or erase a program-protected block (**FMPPEn** bit is set) is prohibited and can optionally generate an interrupt

(by setting the `AMASK` bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in "Non-Volatile Register Programming" on page 532.

8.2.3.3 Interrupts

The Flash memory controller can generate interrupts when the following conditions are observed:

- Programming Interrupt - signals when a program or erase action is complete.
- Access Interrupt - signals when a program or erase action has been attempted on a 2-kB block of memory that is protected by its corresponding **FMPPEn** bit.

The interrupt events that can trigger a controller-level interrupt are defined in the **Flash Controller Masked Interrupt Status (FCMIS)** register (see page 547) by setting the corresponding `MASK` bits. If interrupts are not used, the raw interrupt status is always visible via the **Flash Controller Raw Interrupt Status (FCRIS)** register (see page 544).

Interrupts are always cleared (for both the **FCMIS** and **FCRIS** registers) by writing a 1 to the corresponding bit in the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register (see page 549).

8.2.3.4 Flash Memory Programming

The Stellaris devices provide a user-friendly interface for Flash memory programming. All erase/program operations are handled via three registers: **Flash Memory Address (FMA)**, **Flash Memory Data (FMD)**, and **Flash Memory Control (FMC)**. Note that if the debug capabilities of the microcontroller have been deactivated, resulting in a "locked" state, a recovery sequence must be performed in order to reactivate the debug module. See "Recovering a "Locked" Microcontroller" on page 199.

During a Flash memory operation (write, page erase, or mass erase) access to the Flash memory is inhibited. As a result, instruction and literal fetches are held off until the Flash memory operation is complete. If instruction execution is required during a Flash memory operation, the code that is executing must be placed in SRAM and executed from there while the flash operation is in progress.

Note: When programming Flash memory, the following characteristics of the memory must be considered:

- Only an erase can change bits from 0 to 1.
- A write can only change bits from 1 to 0. If the write attempts to change a 0 to a 1, the write fails and no bits are changed.
- A flash operation can be started before entering Sleep or Deep-sleep mode (using the wait for interrupt instruction, `WFI`), but will not complete while in Sleep or Deep-sleep. Instead, the operation completes after an event has woken the system. This means that you cannot rely on the `PRIS` bit in the **Flash Controller Raw Interrupt Status (FCRIS)** register to actually wake the device from Sleep or Deep-Sleep.

To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the Flash memory write key and the **WRITE** bit (a value of 0xA442.0001) to the **FMC** register.
4. Poll the **FMC** register until the **WRITE** bit is cleared.

To perform an erase of a 1-KB page

1. Write the page address to the **FMA** register.
2. Write the Flash memory write key and the **ERASE** bit (a value of 0xA442.0002) to the **FMC** register.
3. Poll the **FMC** register until the **ERASE** bit is cleared or, alternatively, enable the programming interrupt using the **PMASK** bit in the **FCIM** register.

To perform a mass erase of the Flash memory

1. Write the Flash memory write key and the **MERASE** bit (a value of 0xA442.0004) to the **FMC** register.
2. Poll the **FMC** register until the **MERASE** bit is cleared or, alternatively, enable the programming interrupt using the **PMASK** bit in the **FCIM** register.

8.2.3.5 32-Word Flash Memory Write Buffer

A 32-word write buffer provides the capability to perform faster write accesses to the Flash memory by programming 2 32-bit words at a time, allowing 32 words to be programmed in the same time as 16. The data for the buffered write is written to the **Flash Write Buffer (FWBn)** registers.

The registers are 32-word aligned with Flash memory, and therefore the register **FWB0** corresponds with the address in **FMA** where bits [6:0] of **FMA** are all 0. **FWB1** corresponds with the address in **FMA** + 0x4 and so on. Only the **FWBn** registers that have been updated since the previous buffered Flash memory write operation are written. The **Flash Write Buffer Valid (FWBVAL)** register shows which registers have been written since the last buffered Flash memory write operation. This register contains a bit for each of the 32 **FWBn** registers, where bit[n] of **FWBVAL** corresponds to **FWBn**. The **FWBn** register has been updated if the corresponding bit in the **FWBVAL** register is set.

To program 32 words with a single buffered Flash memory write operation

1. Write the source data to the **FWBn** registers.
2. Write the target address to the **FMA** register. This must be a 32-word aligned address (that is, bits [6:0] in **FMA** must be 0s).
3. Write the Flash memory write key and the **WRBUF** bit (a value of 0xA442.0001) to the **FMC2** register.
4. Poll the **FMC2** register until the **WRBUF** bit is cleared or wait for the **PMIS** interrupt to be signaled.

8.2.3.6 Non-Volatile Register Programming

This section discusses how to update registers that are resident within the Flash memory itself. These registers exist in a separate space from the main Flash memory array and are not affected by an ERASE or MASS ERASE operation. The bits in these registers can be changed from 1 to 0 with a write operation. The register contents are unaffected by any reset condition except power-on reset, which returns the register contents to 0xFFFF.FFFF. By committing the register values using the **COMT** bit in the **FMC** register, the register contents become non-volatile and are therefore retained following power cycling. Once the register contents are committed, the only way to restore the factory default values is to perform the sequence described in “Recovering a “Locked” Microcontroller” on page 199.

With the exception of the **Boot Configuration (BOOTCFG)** register, the settings in these registers can be tested before committing them to Flash memory. For the **BOOTCFG** register, the data to be written is loaded into the **FMD** register before it is committed. The **FMD** register is read only and does not allow the **BOOTCFG** operation to be tried before committing it to non-volatile memory.

Important: The Flash memory resident registers can only have bits changed from 1 to 0 by user programming and can only be committed once. After being committed, these registers can only be restored to their factory default values only by performing the sequence described in “Recovering a “Locked” Microcontroller” on page 199. The mass erase of the main Flash memory array caused by the sequence is performed prior to restoring these registers.

In addition, the **USER_REG0**, **USER_REG1**, **USER_REG2**, **USER_REG3**, and **BOOTCFG** registers each use bit 31 (**NW**) to indicate that they have not been committed and bits in the register may be changed from 1 to 0. Table 8-2 on page 532 provides the **FMA** address required for commitment of each of the registers and the source of the data to be written when the **FMC** register is written with a value of 0xA442.0008. After writing the **COMT** bit, the user may poll the **FMC** register to wait for the commit operation to complete.

Table 8-2. User-Programmable Flash Memory Resident Registers

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPPE0	0x0000.0001	FMPPE0
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1
USER_REG2	0x8000.0002	USER_REG2
USER_REG3	0x8000.0003	USER_REG3
BOOTCFG	0x7510.0000	FMD

8.2.4 EEPROM

The LM4F120B2QR microcontroller includes an EEPROM with the following features:

- 2K bytes of memory accessible as 512 32-bit words
- 32 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block

- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages) per each 2-page block.

8.2.4.1 Functional Description

The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme.

A protection mechanism allows locking EEPROM blocks to prevent writes under a set of circumstances as well as reads under the same or different circumstances. The password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

Blocks

There are 32 blocks of 16 words each in the EEPROM. Bytes and half-words can be read, and these accesses do not have to occur on a word boundary. The entire word is read and any unneeded data is simply ignored. They are writable only on a word basis. To write a byte, it is necessary to read the word value, modify the appropriate byte, and write the word back.

Each block is addressable as an offset within the EEPROM, using a block select register. Each word is offset addressable within the selected block.

The current block is selected by the **EEPROM Current Block (EEBLOCK)** register. The current offset is selected and checked for validity by the **EEPROM Current Offset (EEOFFSET)** register. The application may write the **EEOFFSET** register any time, and it is also automatically incremented when the **EEPROM Read-Write with Increment (EERDWRINC)** register is accessed. However, the **EERDWRINC** register does not increment the block number, but instead wraps within the block.

Blocks are individually protectable. Attempts to read from a block for which the application does not have permission return 0xFFFF.FFFF. Attempts to write into a block for which the application does not have permission results in an error in the **EEPROM Done Status (EEDONE)** register.

Timing Considerations

After enabling or resetting the EEPROM module, software must wait until the `WORKING` bit in the **EEDONE** register is clear before accessing any EEPROM registers.

In the event that there are Flash memory writes or erases and EEPROM writes active, it is possible for the EEPROM process to be interrupted by the Flash memory write/erase and then continue after the Flash memory write is completed. This action may change the amount of time that the EEPROM operation takes.

EEPROM operations must be completed before entering Sleep or Deep-Sleep mode. Ensure the EEPROM operations have completed by checking the **EEPROM Done Status (EEDONE)** register before issuing a `WFI` instruction to enter Sleep or Deep-Sleep.

Reads of words within a block are at direct speed, which means that wait states are automatically generated if the system clock is faster than the speed of the EEPROM. The read access time is specified in Table 23-22 on page 1179.

Writing the **EEOFFSET** register also does not incur any penalties.

Writing the **EEBLOCK** register is not delayed, but any attempt to access data within that block is delayed by 4 clocks after writing **EEBLOCK**. This time is used to load block specific information.

Writes to words within a block are delayed by a variable amount of time. The application may use an interrupt to be notified when the write is done, or alternatively poll for the done status in the **EEDONE** register. The variability ranges from the write timing of the EEPROM to the erase timing of EEPROM, where the erase timing is less than the write timing of most external EEPROMs.

Locking and Passwords

The EEPROM can be locked at both the module level and the block level. The lock is controlled by a password that is stored in the **EEPROM Password (EEPASSn)** registers and can be any 32-bit to 96-bit value other than all 1s. Block 0 is the master block, the password for block 0 protects the control registers as well as all other blocks. Each block can be further protected with a password for that block.

If a password is registered for block 0, then the whole module is locked at reset. The locking behavior is such that blocks 1 to 31 are inaccessible until block 0 is unlocked, and block 0 follows the rules defined by its protection bits. As a result, the **EEBLOCK** register cannot be changed from 0 until block 0 is unlocked.

A password registered with any block, including block 0, allows for protection rules that control access of that block based on whether it is locked or unlocked. Generally, the lock can be used to prevent write accesses when locked or can prevent read and write accesses when locked.

All password protected blocks are locked at reset. To unlock a block, the correct password value must be written to the **EEPROM Unlock (EEUNLOCK)** register by writing to it once, twice, or three times, depending on the size of the password. A block or the module may be re-locked by writing 0xFFFF.FFFF to the **EEUNLOCK** register because 0xFFFF.FFFF is not a valid password.

Protection and Access Control

The protection bits provide discrete control of read and write access for each block which allows various protection models per block, including:

- Without password: Readable and writable at any time. This mode is the default when there is no password.
- Without password: Readable but not writable.
- With password: Readable, but only writable when unlocked by the password. This mode is the default when there is a password.
- With password: Readable or writable only when unlocked.
- With password: Readable only when unlocked, not writable.

Additionally, access protection may be applied based on the processor mode. This configuration allows for supervisor-only access or supervisor and user access, which is the default. Supervisor-only access mode also prevents access by the μ DMA and Debugger.

Additionally, the master block may be used to control access protection for the protection mechanism itself. If access control for block 0 is for supervisor only, then the whole module may only be accessed in supervisor mode.

Note that for blocks 1 to 31, they are inaccessible for read or write if block 0 has a password and it is not unlocked. If block 0 has a master password, then the strictest protection defined for block 0 or an individual block is implemented on the remaining blocks.

Hidden Blocks

Hiding provides a temporary form of protection. Every block except block 0 can be hidden, which prevents all accesses until the next reset.

This mechanism can allow a boot or initialization routine to access some data which is then made inaccessible to all further accesses. Because boot and initialization routines control the capabilities of the application, hidden blocks provide a powerful isolation of the data when debug is disabled.

A typical use model would be to have the initialization code store passwords, keys, and/or hashes to use for verification of the rest of the application. Once performed, the block is then hidden and made inaccessible until the next reset which then re-enters the initialization code.

Power and Reset Safety

Once the **EEDONE** register indicates that a location has been successfully written, the data is retained until that location is written again. There is no power or reset race after the **EEDONE** register indicates a write has completed.

Interrupt Control

The EEPROM module allows for an interrupt when a write completes to prevent the use of polling. The interrupt can be used to drive an application ISR which can then write more words or verify completion. The interrupt mechanism is used any time the **EEDONE** register goes from working to done, whether because of an error or the successful completion of a program or erase operation. This interrupt mechanism works for data writes, writes to password and protection registers, forced erase by the **EEPROM Support Control and Status (EESUPP)** register, and mass erase using the **EEPROM Debug Mass Erase (EEDGBME)** register. The EEPROM interrupt is signaled to the core using the Flash memory interrupt vector. Software can determine that the source of the interrupt was the EEPROM by examining bit 2 of the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register.

Theory of Operation

The EEPROM operates using a traditional bank model which implements EEPROM-type cells, but uses sector erase. Additionally, words are replicated in the blocks to allow 500K+ erase cycles when needed, which means that each word has a latest version. As a result, a write creates a new version of the word in a new location, making the previous value obsolete.

Each sector contains one or more blocks. Each block contains locations for the active copy plus six redundant copies. Passwords, protection bits, and control data are all stored in the blocks.

When a block runs out of room to store the latest version of a word, a copy buffer is used. The copy buffer copies the latest words of each block. The original block is then erased. Finally, the copy buffer contents are copied back to the block. This mechanism ensures that data cannot be lost due to power down, even during an operation. The EEPROM mechanism properly tracks all state information to provide complete safety and protection. Although it should not normally be possible, errors during programming can occur in certain circumstances, for example, the voltage rail dropping during programming. In these cases, the **EESUPP** register can be used to finish an operation as described in the section called "Error During Programming" on page 536.

Manual Copy Buffer Erase

The copy buffer is only used when a main block is full because a word has been written seven times and there is no more room to store its latest version. In this situation, the latest versions of all the words in the block are copied to the copy buffer, allowing the main block to be erased safely, providing power down safety. If the copy buffer itself is full, then it must first be erased, which adds extra time.

By performing a manual erase of the copy buffer, this overhead does not occur during a future write access. The `EREQ` bit in the **EESUPP** register is set if the copy buffer must be erased. If so, the `START` bit can be written by the application to force the erase at a more convenient time. The **EEDONE** and **EEINT** registers can be used to detect completion.

Error During Programming

Operations such as data-write, password set, protection set, and copy buffer erase may perform multiple operations. For example, a normal write performs two underlying writes: the control word write and the data write. If the control word writes but the data fails (for example, due to a voltage drop), the overall write fails with indication provided in the **EEDONE** register. Failure and the corrective action is broken down by the type of operation:

- If a normal write fails such that the control word is written but the data fails to write, the safe course of action is to retry the operation once the system is otherwise stable, for example, when the voltage is stabilized. After the retry, the control word and write data are advanced to the next location.
- If a password or protection write fails, the safe course of action is to retry the operation once the system is otherwise stable. In the event that multi-word passwords may be written outside of a manufacturing or bring-up mode, care must be taken to ensure all words are written in immediate succession. If not, then partial password unlock would need to be supported to recover.
- If the word write requires the block to be written to the copy buffer, then it is possible to fail or lose power during the subsequent operations. A control word mechanism is used to track what step the EEPROM was in if a failure occurs. If not completed, the **EESUPP** register indicates the partial completion, and the **EESUPP** `START` bit can be written to allow it to continue to completion.
- If a copy buffer erase fails or power is lost while erasing, the **EESUPP** register indicates it is not complete and allows it to be restarted

After a reset and prior to writing any data to the EEPROM, software must read the **EESUPP** register and check for the presence of any error condition which may indicate that a write or erase was in progress when the system was reset due to a voltage drop. If either the `PRETRY` or `ERETRY` bits are set, the peripheral should be reset by setting and then clearing the `R0` bit in the **EEPROM Software Reset (SREEPROM)** register and waiting for the `WORKING` bit in the **EEDONE** register to clear before again checking the **EESUPP** register for error indicators. This procedure should allow the EEPROM to recover from the write or erase error. In very isolated cases, the **EESUPP** register may continue to register an error after this operation, in which case the reset should be repeated. After recovery, the application should rewrite the data which was being programmed when the initial failure occurred.

Endurance

Endurance is per meta-block which is 2 blocks. Endurance is measured in two ways:

1. To the application, it is the number of writes that can be performed.
2. To the microcontroller, it is the number of erases that can be performed on the meta-block.

Because of the second measure, the number of writes depends on how the writes are performed. For example:

- One word can be written more than 500K times, but, these writes impact the meta-block that the word is within. As a result, writing one word 500K times, then trying to write a nearby word 500K times is not assured to work. To ensure success, the words should be written more in parallel.
- All words can be written in a sweep with a total of more than 500K sweeps which updates all words more than 500K times.
- Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. For example, offset 0 could be written 3 times, then offset 1 could be written 2 times, then offset 2 is written 4 times, then offset 1 is written twice, then offset 0 is written again. As a result, all 3 offsets would have 4 writes at the end of the sequence. This kind of balancing within 7 writes maximizes the endurance of different words within the same meta-block.

8.2.4.2 EEPROM Initialization and Configuration

Before writing to any EEPROM registers, the clock to the EEPROM module must be enabled, see page 389.

A common setup is as follows:

- Block 0 has a password.
- Block 0 is readable by all, but only writable when unlocked.
- Block 0 has an “ID” and other public data.

In this configuration, the ID is readable any time, but the rest of the EEPROM is locked to accesses by the application. The rest of the blocks only become available when parts of the application that are allowed to access the EEPROM choose to unlock block 0.

8.3 Register Map

Table 8-3 on page 537 lists the ROM Controller register and the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The Flash memory register offsets are relative to the Flash memory control base address of 0x400F.D000. The EEPROM registers are relative to the EEPROM base address of 0x400A.F000. The ROM and Flash memory protection register offsets are relative to the System Control base address of 0x400F.E000.

Table 8-3. Flash Register Map

8.4 Flash Memory Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

Register 1: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned CPU byte address and specifies which block is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

Flash Memory Address (FMA)

Base 0x400F.D000

Offset 0x000

Type R/W, reset 0x0000.0000

Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 540). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 541) is written to the specified address.

This register must be the final register written and initiates the memory operation. The four control bits in the lower byte of this register are used to initiate memory operations.

Care must be taken not to set multiple control bits as the results of such an operation are unpredictable.

0	WRBUF	R/W	0	Buffered Flash Memory Write This bit is used to start a buffered write to Flash memory.

Value Description

- | | |
|---|--|
| 1 | Set this bit to write the data stored in the FWBn registers to the location specified by the contents of the FMA register.
When read, a 1 indicates that the previous buffered Flash memory write access is not complete. |
| 0 | A write of 0 has no effect on the state of this bit.
When read, a 0 indicates that the previous buffered Flash memory write access is complete. |

For information on programming time, see "Flash Memory and EEPROM" on page 1179.

Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030

This register provides a bitwise status of which **FWB_n** registers have been written by the processor since the last write of the Flash memory write buffer. The entries with a 1 are written on the next write of the Flash memory write buffer. This register is cleared after the write operation by hardware. A protection violation on the write operation also clears this status.

Software can program the same 32 words to various Flash memory locations by setting the **FWB_[n]** bits after they are cleared by the write operation. The next write operation then uses the same data as the previous one. In addition, if a **FWB_n** register change should not be written to Flash memory, software can clear the corresponding **FWB_[n]** bit to preserve the existing data when the next write operation occurs.

Bit/Field	Name	Type	Reset	Description
31:0	FWB[n]	R/W	0x0	Flash Memory Write Buffer

Value Description

- | | |
|---|--|
| 1 | The corresponding FWB_n register has been updated since the last buffer write operation and is ready to be written to Flash memory. |
| 0 | The corresponding FWB_n register has no new data to be written. |

Bit 0 corresponds to **FWB₀**, offset 0x100, and bit 31 corresponds to **FWB₃₁**, offset 0x13C.

Register 9: Flash Write Buffer n (FWBn), offset 0x100 - 0x17C

These 32 registers hold the contents of the data to be written into the Flash memory on a buffered Flash memory write operation. The offset selects one of the 32-bit registers. Only **FWBn** registers that have been updated since the preceding buffered Flash memory write operation are written into the Flash memory, so it is not necessary to write the entire bank of registers in order to write 1 or 2 words. The **FWBn** registers are written into the Flash memory with the **FWB0** register corresponding to the address contained in **FMA**. **FWB1** is written to the address **FMA+0x4** etc. Note that only data bits that are 0 result in the Flash memory being modified. A data bit that is 1 leaves the content of the Flash memory bit at its previous value.

Register 10: Flash Size (FSIZE), offset 0xFC0

This register indicates the size of the on-chip Flash memory.

Important: This register should be used to determine the size of the Flash memory that is implemented on this microcontroller. However, to support legacy software, the **DC0** register is available. A read of the **DC0** register correctly identifies legacy memory sizes. Software must use the **FSIZE** register for memory sizes that are not listed in the **DC0** register description.

Register 12: ROM Software Map (ROMSWMAP), offset 0xFCC

This register indicates the presence of third-party software in the on-chip ROM.

Important: This register should be used to determine the presence of third-party software in the on-chip ROM on this microcontroller. However, to support legacy software, the **NVMSTAT** register is available. A read of the **TPSW** bit in the **NVMSTAT** register correctly identifies the presence of legacy third-party software. Software should use the **ROMTPSW** register for software that is not on legacy devices.

8.5 EEPROM Register Descriptions (EEPROM Offset)

This section lists and describes the EEPROM registers, in numerical order by address offset. Registers in this section are relative to the EEPROM base address of 0x400A.F000.

Note that the EEPROM module clock must be enabled before the registers can be programmed (see page 389). There must be a delay of 3 system clocks after the EEPROM module clock is enabled before any EEPROM module registers are accessed. In addition, after enabling or resetting the EEPROM module, software must wait until the **WORKING** bit in the **EEDONE** register is clear before accessing any EEPROM registers.

Register 13: EEPROM Size Information (EESIZE), offset 0x000

The **EESIZE** register indicates the number of 16-word blocks and 32-bit words in the EEPROM.

EEPROM Size Information (EESIZE)

26:16	BLKCNT	RO	0x20	Number of 16-Word Blocks This value encoded in this field describes the number of 16-word blocks in the EEPROM.
15:0	WORDCNT	RO	0x200	Number of 32-Bit Words This value encoded in this field describes the number of 32-bit words in the EEPROM.

Register 14: EEPROM Current Block (EEBLOCK), offset 0x004

The **EEBLOCK** register is used to select the EEPROM block for subsequent reads, writes, and protection control. The value is a block offset into the EEPROM, such that the first block is 0, then second block is 1, etc. Each block contains 16 words. Attempts to set an invalid block causes the **BLOCK** field to be configured to 0. To verify that the intended block is being accessed, software can read the **BLOCK** field after it has been written. An invalid block can be either a non-existent block or a block that has been hidden using the **EEHIDE** register. Note that block 0 cannot be hidden.

EEPROM Current Block (EEBLOCK)

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	BLOCK	R/W	0x0000	<p>Current Block</p> <p>This field specifies the block in the EEPROM that is selected for subsequent accesses. Once this field is configured, the read-write registers operate against the specified block, using the EEOFFSET register to select the word within the block. Additionally, the protection and unlock registers are used for the selected block. The maximum value that can be written into this register is determined by the block count, as indicated by the EESIZE register. Attempts to write this field larger than the maximum number of blocks or to a locked block causes this field to be configured to 0.</p>

Register 15: EEPROM Current Offset (EEOFFSET), offset 0x008

The **EEOFFSET** register is used to select the EEPROM word to read or write within the block selected by the **EEBLOCK** register. The value is a word offset into the block. Because accesses to the **EERDWRINC** register change the offset, software can read the contents of this register to determine the current offset.

EEPROM Current Offset (EEOFFSET)

Base 0x400A.F000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	OFFSET	R/W	0x0	Current Address Offset This value is the current address specified as an offset into the block selected by the EEBLOCK register. Once configured, the read-write registers, EERDRWR and EERDWRINC , operate against that address. The offset is automatically incremented by the EERDWRINC register, with wrap around within the block, which means the offset is incremented from 15 back to 0.

Register 16: EEPROM Read-Write (EERDWR), offset 0x010

The **EERDWR** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error.

EEPROM Read-Write (EERDWR)

Base 0x400A.F000

Offset 0x010

Bit/Field	Name	Type	Reset	Description
31:0	VALUE	R/W	-	EEPROM Read or Write Data On a read, this field contains the value at the word pointed to by EEOFFSET . On a write, this field contains the data to be stored at the word pointed to by EEOFFSET . For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the EEDONE register indicates failure.

Register 17: EEPROM Read-Write with Increment (EERDWRINC), offset 0x014

The **EERDWRINC** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers, and then increment the **OFFSET** field in the **EEOFFSET** register. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error. In any case, the **OFFSET** field is incremented. If the last value is reached, **OFFSET** wraps around to 0 and points to the first word.

Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	VALUE	R/W	-	<p>EEPROM Read or Write Data with Increment</p> <p>On a read, this field contains the value at the word pointed to by EEOFFSET. On a write, this field contains the data to be stored at the word pointed to by EEOFFSET. For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the EEDONE register indicates failure.</p> <p>Regardless of error, the OFFSET field in the EEOFFSET register is incremented by 1, and the value wraps around if the last word is reached.</p>

Register 18: EEPROM Done Status (EEDONE), offset 0x018

The **EEDONE** register indicates the successful or failed completion of a write using the **EERDWR** or **EERDWRINC** register, protection set using the **EEPROT** register, password registered using the **EEPASS** register, support control using the **EESUPP** register, or a debug mass erase using the **EEDBGME** register. The **EEDONE** register can be used in conjunction with the **EEINT** register to generate an interrupt to report the status. The normal usage is to poll the **EEDONE** register or read the register after an interrupt is triggered. When **EEDONE&1** is true, then write is still in progress. When **EEDONE&1** is not true, then the value of **EEDONE** indicates the completion status. If **EEDONE==0**, then the write completed successfully. If **EEDONE!=0**, then an error occurred as indicated by which bit is set. If an error occurs, corrective action may be taken as explained on page 565.

EEPROM Done Status (EEDONE)

31:9	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	INVPL	RO	0	Invalid Program Voltage Level Value Description 1 An error occurred during programming due to the voltage level dropping below the level required for EEPROM programming. This operation can be retried, however the voltage must be stabilized before retrying. 0 No error
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	WRBUSY	RO	0	Write Busy Value Description 1 An attempt to access the EEPROM was made while a write was in progress. 0 No error

Bit/Field	Name	Type	Reset	Description
4	NOPERM	RO	0	Write Without Permission Value Description 1 An attempt was made to write without permission. This error can result because the block is locked, the write violates the programmed access protection, or when an attempt is made to write a password when the password has already been written. 0 No error
3	WKCOPY	RO	0	Working on a Copy Value Description 1 A write is in progress and is waiting for the EEPROM to copy to or from the copy buffer. 0 The EEPROM is not copying.
2	WKERASE	RO	0	Working on an Erase Value Description 1 A write is in progress and the original block is being erased after being copied. 0 The EEPROM is not erasing.
1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WORKING	RO	0	EEPROM Working Value Description 1 The EEPROM is performing the requested operation. 0 The EEPROM is not working.

Register 19: EEPROM Support Control and Status (EESUPP), offset 0x01C

The **EESUPP** register indicates if internal operations are required because an internal copy buffer must be erased or a programming failure has occurred and the operation must be completed. These conditions are explained below as well as in more detail in the section called “Manual Copy Buffer Erase” on page 535 and the section called “Error During Programming” on page 536.

- The **EREQ** bit is set if the internal copy buffer must be erased the next time it is used because it is full. To avoid the delay of waiting for the copy buffer to be erased on the next write, it can be erased manually using this register by setting the **START** bit.
- If either **PRETRY** or **ERETRY** is set indicating that an operation must be completed, setting the **START** bit causes the operation to be performed again.

These bits are not changed by reset, so any condition that occurred before a reset is still indicated after a reset.

EEPROM Support Control and Status (EESUPP)

Base 0x400A.F000

Offset 0x01C

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	PRETRY	RO	-	Programming Must Be Retried Value Description 1 Programming from a copy in either direction failed to complete and must be restarted by setting the START bit. 0 Programming has not failed.
2	ERETRY	RO	-	Erase Must Be Retried Value Description 1 Erasing failed to complete and must be restarted by setting the START bit. If the failed erase is due to the erase of a main buffer, the copy will be performed after the erase completes successfully. 0 Erasing has not failed.

Bit/Field	Name	Type	Reset	Description
1	EREQ	RO	-	<p>Erase Required</p> <p>Value Description</p> <p>1 An erase of the copy buffer is required.</p> <p>0 The copy buffer has available space.</p>
0	START	R/W	0	<p>Start Erase</p> <p>Setting this bit starts error recovery if the PRETRY or ERETRY bit is set. If both the PRETRY and the ERETRY bits are clear, setting this bit starts erasing the copy buffer if EREQ is set. If none of the other bits in this register are set, setting this bit is ignored. After this bit is set, the WORKING bit in the EEDONE register is set and is cleared when the operation is complete. In addition, the EEINT register can be used to generate an interrupt on completion.</p> <p>If this bit is set while an operation is in progress, the write is ignored. The START bit is automatically cleared when the operation completes.</p>

Register 20: EEPROM Unlock (EEUNLOCK), offset 0x020

The **EEUNLOCK** register can be used to unlock the whole EEPROM or a single block using a password. Unlocking is only required if a password is registered using the **EEPASSn** registers for the block that is selected by the **EEBLOCK** register. If block 0 has a password, it locks the remaining blocks from any type of access, but uses its own protection mechanism, for example readable, but not writable when locked. In addition, if block 0 has a password, it must be unlocked before unlocking any other block.

The **EEUNLOCK** register is written between 1 and 3 times to form the 32-bit, 64-bit, or 96-bit password registered using the **EEPASSn** registers. The value used to configure the **EEPASS0** register must always be written last. For example, for a 96-bit password, the value used to configure the **EEPASS2** register must be written first followed by the **EEPASS1** and **EEPASS0** register values. The block or the whole EEPROM can be re-locked by writing 0xFFFF.FFFF to this register.

In the event that an invalid value is written to this register, the block remains locked. The state of the EEPROM lock can be determined by reading back the **EEUNLOCK** register. If a multi-word password is set and the number of words written is incorrect, writing 0xFFFF.FFFF to this register reverts the EEPROM lock to the locked state, and the proper unlock sequence can be retried.

Note that the internal logic is balanced to prevent any electrical or time-based attack being used to find the correct password or its length.

EEPROM Unlock (EEUNLOCK)

Bit/Field	Name	Type	Reset	Description
31:0	UNLOCK	R/W	-	EEPROM Unlock

Value Description

1	The EEPROM is unlocked.
0	The EEPROM is locked.

The EEPROM is locked if the block referenced by the **EEBLOCK** register has a password registered, or if the master block (block 0) has a password. Unlocking is performed by writing the password to this register. The block or the EEPROM stays unlocked until it is locked again or until the next reset. It can be locked again by writing 0xFFFF.FFFF to this register.

Register 21: EEPROM Protection (EEPROT), offset 0x030

The **EEPROT** register is used to set or read the protection for the current block, as selected by the **EEBLOCK** register. Protection and access control is used to determine when a block's contents can be read or written.

EEPROM Protection (EEPROT)

Base 0x400A.F000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ACC	R/W	0	Access Control Value Description 1 Only supervisor code may access this block of the EEPROM. μ DMA and Debug are also prevented from accessing the EEPROM. 0 Both user and supervisor code may access this block of the EEPROM. If this bit is set for block 0, then the whole EEPROM may only be accessed by supervisor code.
2:0	PROT	R/W	0x0	Protection Control The Protection bits control what context is needed for reading and writing the block selected by the EEBLOCK register, or if block 0 is selected, all blocks. The following values are allowed: Value Description 0x0 This setting is the default. If there is no password, the block is not protected and is readable and writable. If there is a password, the block is readable, but only writable when unlocked. 0x1 If there is a password, the block is readable or writable only when unlocked. This value has no meaning when there is no password. 0x2 If there is no password, the block is readable, not writable. If there is a password, the block is readable only when unlocked, but is not writable under any conditions. 0x3 Reserved

Register 22: EEPROM Password (EEPASS0), offset 0x034**Register 23: EEPROM Password (EEPASS1), offset 0x038****Register 24: EEPROM Password (EEPASS2), offset 0x03C**

The **EEPASSn** registers are used to configure a password for a block. A password may only be set once and cannot be changed. The password may be 32-bits, 64-bits, or 96-bits. Each word of the password can be any 32-bit value other than 0xFFFF.FFFF (all 1s). To set a password, the **EEPASS0** register is written to with a value other than 0xFFFF.FFFF. When the write completes, as indicated in the **EEDONE** register, the application may choose to write to the **EEPASS1** register with a value other than 0xFFFF.FFFF. When that write completes, the application may choose to write to the **EEPASS2** register with a value other than 0xFFFF.FFFF to create a 96-bit password. The registers do not have to be written consecutively, and the **EEPASS1** and **EEPASS2** registers may be written at a later date. Based on whether 1, 2, or all 3 registers have been written, the unlock code also requires the same number of words to unlock.

Note: Once the password is written, the block is not actually locked until either a reset occurs or 0xFFFF.FFFF is written to **EEUNLOCK**.

EEPROM Password (EEPASS0)

Base 0x400A.F000

Offset 0x034

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	PASS	R/W	-	Password This register reads as 0x1 if a password is registered for this block and 0x0 if no password is registered. A write to this register if it reads as 0x0 sets the password. If an attempt is made to write to this register when it reads as 0x1, the write is ignored and the NOPERM bit in the EEDONE register is set.

Register 25: EEPROM Interrupt (EEINT), offset 0x040

The **EEINT** register is used to control whether an interrupt should be generated when a write to EEPROM completes as indicated by the **EEDONE** register value changing from 0x1 to any other value. If the **INT** bit in this register is set, the **ERIS** bit in the **Flash Controller Raw Interrupt Status (FCRIS)** register is set whenever the **EEDONE** register value changes from 0x1 as the Flash memory and the EEPROM share an interrupt vector.

EEPROM Interrupt (EEINT)

0	INT	R/W	0	Interrupt Enable
				Value Description
				1 An interrupt is generated when the EEDONE register transitions from 1 to 0 or an error occurs. The EEDONE register provides status after a write to an offset location as well as a write to the password and protection bits.
				0 No interrupt is generated.

Register 26: EEPROM Block Hide (EEHIDE), offset 0x050

The **EEHIDE** register is used to hide one or more blocks other than block 0. Once hidden, the block is not accessible until the next reset. This model allows initialization code to have access to data which is not visible to the rest of the application. This register also provides for additional security in that there is no password to search for in the code or data.

Value Description

- | | |
|---|---|
| 1 | The block number that corresponds to the bit number is hidden. A hidden block cannot be accessed, and the OFFSET value in the EEBLOCK register cannot be set to that block number. If an attempt is made to configure the OFFSET field to a hidden block, the EEBLOCK register is cleared.
Any attempt to clear a bit in this register that is set is ignored. |
| 0 | The corresponding block is not hidden. |

0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
---	----------	----	---	---

Register 27: EEPROM Debug Mass Erase (EEDBGME), offset 0x080

The **EEDBGME** register is used to mass erase the EEPROM block back to its default state from the factory. This register is intended to be used only for debug and test purposes, not in production environments. The erase takes place in such a way as to be secure. It first erases all data and then erases the protection mechanism. This register can only be written from supervisor mode by the core, and can also be written by the Stellaris debug controller when enabled. A key is used to avoid accidental use of this mechanism. Note that if a power down takes place while erasing, the mechanism should be used again to complete the operation. Powering off prematurely does not expose secured data.

To start a mass erase, the whole register must be written as 0xE37B.0001. The register reads back as 0x1 until the erase is fully completed at which time it reads as 0x0. The **EEDONE** register is set to 0x1 when the erase is started and changes to 0x0 or an error when the mass erase is complete.

EEPROM Debug Mass Erase (EEDBGME)

8.6 Memory Register Descriptions (System Control Offset)

The remainder of this section lists and describes the registers that reside in the System Control address space, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

Register 29: ROM Control (RMCTL), offset 0x0F0

This register provides control of the ROM controller state. This register offset is relative to the System Control base address of 0x400F.E000.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

0	BA	R/W1C	1	Boot Alias
---	----	-------	---	------------

Value Description

- | | |
|---|---|
| 1 | The microcontroller's ROM appears at address 0x0. |
| 0 | The Flash memory is at address 0x0. |

This bit is cleared by writing a 1 to this bit position.

Register 30: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

Note: The **FMPRE0** register is aliased for backwards compatibility.

Note: Offset is relative to System Control base address of 0x400F.E000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits).

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter.

Each **FMPREn** register controls a 64K block. For additional information, see the "Flash Memory Protection" section.

■ FMPRE0: 0 to 64 KB

Flash Memory Protection Read Enable 0 (FMPRE0)

Base 0x400F.E000
Offset 0x130 and 0x200
Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFF.FFFF	Flash Read Enable Each bit configures a 2-KB flash block to be read only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Register 31: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

Note: The **FMPPE0** register is aliased for backwards compatibility.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the read-only protection bits).

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see the "Flash Memory Protection" section.

Each **FMPPEn** register controls a 64K block. For additional information, see the "Flash Memory Protection" section.

■ FMPPE0: 0 to 64 KB

Flash Memory Protection Program Enable 0 (FMPPE0)

Base 0x400F.E000
Offset 0x134 and 0x400
Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	R/W	0xFFFF.FFFF	Flash Programming Enable Each bit configures a 2-KB flash block to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Register 32: Boot Configuration (BOOTCFG), offset 0x1D0

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides configuration of a GPIO pin to enable the ROM Boot Loader as well as a write-once mechanism to disable external debugger access to the device. Upon reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal from Ports A-H as configured by the bits in this register. At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

The **DBG0** bit is cleared by the factory and the **DBG1** bit is set, which enables external debuggers. Clearing the **DBG1** bit disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The **NW** bit indicates that the register has not yet been committed and is controlled through hardware to ensure that the register is only committed once. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. The only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter.

Bit/Field	Name	Type	Reset	Description
1	DBG1	R/W	1	Debug Control 1 The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.
0	DBG0	R/W	0	Debug Control 0 The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.

Register 33: User Register 0 (USER_REG0), offset 0x1E0

Register 34: User Register 1 (USER_REG1), offset 0x1E4

Register 35: User Register 2 (USER_REG2), offset 0x1E8

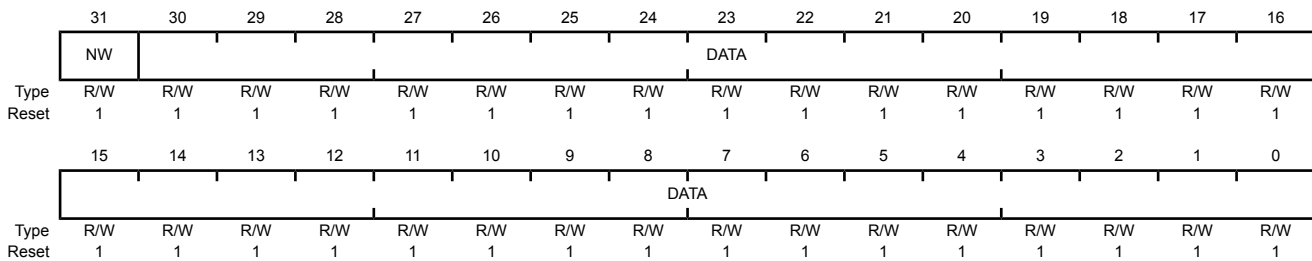

Register 36: User Register 3 (USER_REG3), offset 0x1EC

Note: Offset is relative to System Control base address of 0x400FE000.

These registers each provide 31 bits of user-defined data that is non-volatile and can only be committed once. Bit 31 indicates that the register is available to be committed and is controlled through hardware to ensure that the register is only committed once. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device. The only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG section.

User Register 0 (USER_REG0)

30:0	DATA	R/W	0x7FFF.FFFF	User Data Contains the user data value. This field is initialized to all 1s and can only be committed once.

9 Micro Direct Memory Access (μDMA)

The LM4F120B2QR microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μDMA). The μDMA controller provides a way to offload data transfer tasks from the Cortex™-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The μDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μDMA controller provides the following features:

- ARM® PrimeCell® 32-channel configurable μDMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
 - Basic for simple transfer scenarios
 - Ping-pong for continuous data flow
 - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
 - Independently configured and operated channels
 - Dedicated channels for supported on-chip modules
 - Flexible channel assignments
 - One channel each for receive and transmit path for bidirectional modules
 - Dedicated channel for software-initiated transfers
 - Per-channel configurable priority scheme
 - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between μDMA controller and the processor core
 - μDMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests

- Interrupt on transfer completion, with a separate interrupt per channel

9.1 Block Diagram

Figure 9-1. μ DMA Block Diagram

9.2 Functional Description

The μ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M4F processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The μ DMA controller's usage of the bus is always subordinate to the processor core, so it never holds up a bus transaction by the processor. Because the μ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly enhance the ability of the processor core and the μ DMA controller to efficiently share the on-chip bus, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allow both the processor core and the μ DMA controller to access the bus and perform simultaneous data transfers.

The μ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the μ DMA controller.

Each peripheral function that is supported has a dedicated channel on the μ DMA controller that can be configured independently. The μ DMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the μ DMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The μ DMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the μ DMA controller re-arbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a μ DMA service request.

9.2.1 Channel Assignments

Each DMA channel has up to five possible assignments which are selected using the **DMA Channel Map Select n (DMACHMAPn)** registers with 4-bit assignment fields for each μ DMA channel.

Table 9-1 on page 583 shows the μ DMA channel mapping. The Enc. column shows the encoding for the respective **DMACHMAPn** bit field. Encodings 0x5 - 0xF are all reserved. To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, Enc. 0 is equivalent to a **DMACHASGN** bit being clear, and Enc. 1 is equivalent to a **DMACHASGN** bit being set. If the **DMACHASGN** register is read, bit fields return 0 if the corresponding **DMACHMAPn** register field value are equal to 0, otherwise they return 1 if the corresponding **DMACHMAPn** register field values are not equal to 0. The Type indication in the table indicates if a particular peripheral uses a single request (S), burst request (B) or either (SB).

Note: Channels noted in the table as "Available for software" may be assigned to peripherals in the future. However, they are currently available for software use. Channel 30 is dedicated for software use.

The USB endpoints mapped to μ DMA channels 0-3 can be changed with the **USBDMASEL** register (see page 1126).

9.2.2 Priority

The μ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

9.2.3 Arbitration Size

When a μ DMA channel requests a transfer, the μ DMA controller arbitrates among all the channels making a request and services the μ DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before re-arbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the μ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority μ DMA channel uses a large arbitration size, the latency for higher priority channels is increased because the μ DMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of μ DMA channel priority, not arbitration for the bus. When the μ DMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the μ DMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

9.2.4 Request Types

The μ DMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The μ DMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the μ DMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 9-2 on page 585, which shows how each peripheral supports the two request types.

Table 9-2. Request Type Support

Peripheral	Single Request Signal	Burst Request Signal
ADC	None	Sequencer IE bit
General-Purpose Timer	Raw interrupt pulse	None
GPIO	Raw interrupt pulse	None
SSI TX	TX FIFO Not Full	TX FIFO Level (fixed at 4)
SSI RX	RX FIFO Not Empty	RX FIFO Level (fixed at 4)
UART TX	TX FIFO Not Full	TX FIFO Level (configurable)
UART RX	RX FIFO Not Empty	RX FIFO Level (configurable)
USB TX	None	FIFO TXRDY
USB RX	None	FIFO RXRDY

9.2.4.1 Single Request

When a single request is detected, and not a burst request, the μ DMA controller transfers one item and then stops to wait for another request.

9.2.4.2 Burst Request

When a burst request is detected, the μ DMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached. A burst transfer runs to completion once it is started, and cannot be interrupted, even by a higher priority channel. Burst transfers complete in a shorter time than the same number of non-burst transfers.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the μ DMA controller only responds to burst requests for that channel.

9.2.5 Channel Configuration

The μ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each μ DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 9-3 on page 586 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table, and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

Table 9-3. Control Structure Memory Map

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary
0x200	0, Alternate
0x210	1, Alternate
...	...
0x3F0	31, Alternate

Table 9-4 shows an individual control structure entry in the control table. Each entry is aligned on a 16-byte boundary. The entry contains four long words: the source end pointer, the destination end pointer, the control word, and an unused entry. The end pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

Table 9-4. Channel Control Structure

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag

- Transfer mode

The control word and each field are described in detail in “ μ DMA Channel Control Structure” on page 604. The μ DMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer mode indicates "stopped." Because the control word is modified by the μ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a μ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set (DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete μ DMA transfer, the controller automatically disables the channel.

9.2.6 Transfer Modes

The μ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

9.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the μ DMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the μ DMA controller updates the control word to set the mode to Stop.

9.2.6.2 Basic Mode

In Basic mode, the μ DMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a μ DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only the number of transfers specified by the `ARBSIZE` field in the **DMA Channel Control Word (DMACHCTL)** register is transferred on a software request, even if there is more data to transfer.

When all of the items have been transferred using Basic mode, the μ DMA controller sets the mode for that channel to Stop.

9.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the μ DMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the μ DMA controller sets the mode for that channel to Stop.

9.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the μ DMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and

alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 9-2 on page 588 for an example showing operation in Ping-Pong mode.

Figure 9-2. Example of Ping-Pong μ DMA Transaction

9.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather μ DMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The μ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Auto transfer mode. Once the last transfer is performed using Auto mode, the μ DMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a μ DMA request.

By programming the μ DMA controller using this method, a set of arbitrary transfers can be performed based on a single μ DMA request.

Refer to Figure 9-3 on page 590 and Figure 9-4 on page 591, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory is copied together into one buffer. Figure 9-3 on page 590 shows how the application sets up a μ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-4 on page 591 shows the sequence as the μ DMA controller performs the three sets of copy operations. First, using the primary control structure, the μ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the μ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

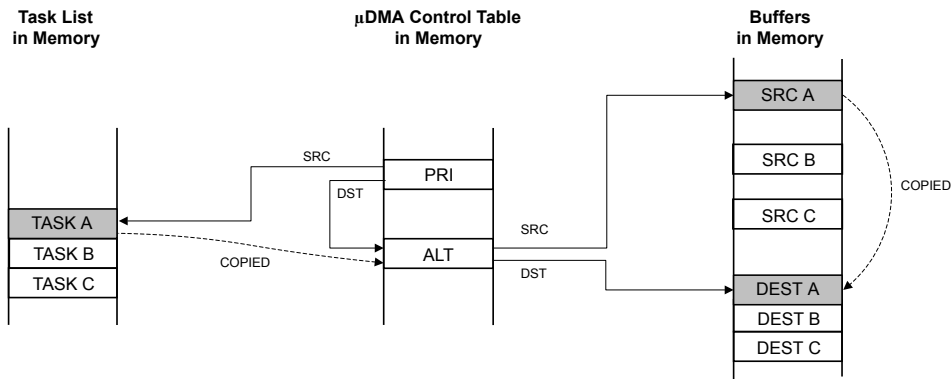

Figure 9-3. Memory Scatter-Gather, Setup and Configuration

NOTES:

1. Application has a need to copy data items from three separate locations in memory into one combined buffer.
2. Application sets up μ DMA "task list" in memory, which contains the pointers and control configuration for three μ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the μ DMA controller.

Figure 9-4. Memory Scatter-Gather, μ DMA Copy Sequence

Using the channel's primary control structure, the μ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer C to the destination buffer.

9.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a μ DMA request. Upon detecting a request from the peripheral, the μ DMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the next transfer is started only if the peripheral again asserts a μ DMA request. The μ DMA controller continues to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt is generated only after the last transfer.

By using this method, the μ DMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 9-5 on page 593 and Figure 9-6 on page 594, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 9-5 on page 593 shows how the application sets up a μ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-6 on page 594 shows the sequence as the μ DMA controller performs the three sets of copy operations. First, using the primary control structure, the μ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the μ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 9-5. Peripheral Scatter-Gather, Setup and Configuration

NOTES:

1. Application has a need to copy data items from three separate locations in memory into a peripheral data register.
2. Application sets up μ DMA "task list" in memory, which contains the pointers and control configuration for three μ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the μ DMA controller.

Figure 9-6. Peripheral Scatter-Gather, μ DMA Copy Sequence

Using the channel's primary control structure, the μ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer A to the peripheral data register.

Using the channel's primary control structure, the μ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer B to the peripheral data register.

Using the channel's primary control structure, the μ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer C to the peripheral data register.

9.2.7 Transfer Size and Increment

The μ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 9-5 shows the configuration to read from a peripheral that supplies 8-bit data.

Table 9-5. μ DMA Read Example: 8-Bit Peripheral

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

9.2.8 Peripheral Interface

Each peripheral that supports μ DMA has a single request and/or burst request signal that is asserted when the peripheral is ready to transfer data (see Table 9-2 on page 585). The request signal can be disabled or enabled using the **DMA Channel Request Mask Set (DMAREQMASET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The μ DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the μ DMA channel is configured correctly and enabled, and the peripheral asserts the request signal, the μ DMA controller begins the transfer.

Note: When using μ DMA to transfer data to and from a peripheral, the peripheral must disable all interrupts to the NVIC.

When a μ DMA transfer is complete, the μ DMA controller generates an interrupt, see “Interrupts and Errors” on page 596 for more information.

For more information on how a specific peripheral interacts with the μ DMA controller, refer to the DMA Operation section in the chapter that discusses that peripheral.

9.2.9 Software Request

One μ DMA channel is dedicated to software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a μ DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral μ DMA channel, then the completion interrupt occurs on the interrupt vector for the peripheral instead of the software interrupt vector. Any channel may be used for software requests as long as the corresponding peripheral is not using μ DMA for data transfer.

9.2.10 Interrupts and Errors

When a μ DMA transfer is complete, the μ DMA controller generates a completion interrupt on the interrupt vector of the peripheral. Therefore, if μ DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the μ DMA transfer completion interrupt. If the transfer uses the software μ DMA channel, then the completion interrupt occurs on the dedicated software μ DMA interrupt vector (see Table 9-6 on page 596).

When μ DMA is enabled for a peripheral, the μ DMA controller stops the normal transfer interrupts for a peripheral from reaching the interrupt controller (the interrupts are still reported in the peripheral's interrupt registers). Thus, when a large amount of data is transferred using μ DMA, instead of receiving multiple interrupts from the peripheral as data flows, the interrupt controller receives only one interrupt when the transfer is complete. Unmasked peripheral error interrupts continue to be sent to the interrupt controller.

When a μ DMA channel generates a completion interrupt, the `CHIS` bit corresponding to the peripheral channel is set in the **DMA Channel Interrupt Status (DMACHIS)** register (see page 631). This register can be used by the peripheral interrupt handler code to determine if the interrupt was caused by the μ DMA channel or an error event reported by the peripheral's interrupt registers. The completion interrupt request from the μ DMA controller is automatically cleared when the interrupt handler is activated.

If the μ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the μ DMA channel that caused the error and generates an interrupt on the μ DMA error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit is set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

Table 9-6 shows the dedicated interrupt assignments for the μ DMA controller.

Table 9-6. μ DMA Interrupt Assignments

Interrupt	Assignment
46	μ DMA Software Channel Transfer
47	μ DMA Error

9.3 Initialization and Configuration

9.3.1 Module Initialization

Before the μ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. Enable the μ DMA clock using the **RCGCDMA** register (see page 377).
2. Enable the μ DMA controller by setting the `MASTEREN` bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

9.3.2 Configuring a Memory-to-Memory Transfer

μDMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

9.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μDMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μDMA controller to recognize requests for this channel.

9.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 9-7.

Table 9-7. Channel Control Structure Offsets for Channel 30

Offset	Description
Control Table Base + 0x1E0	Channel 30 Source End Pointer
Control Table Base + 0x1E4	Channel 30 Destination End Pointer
Control Table Base + 0x1E8	Channel 30 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 9-8.

Table 9-8. Channel Control Word Configuration for Memory Transfer Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:18	0	Reserved

Table 9-8. Channel Control Word Configuration for Memory Transfer Example (continued)

Field in DMACHCTL	Bits	Value	Description
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

9.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The μ DMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

9.3.3 Configuring a Peripheral for Simple Transmit

This example configures the μ DMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses μ DMA channel 7.

9.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

9.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using μ DMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 9-9.

Table 9-9. Channel Control Structure Offsets for Channel 7

Offset	Description
Control Table Base + 0x070	Channel 7 Source End Pointer

Table 9-9. Channel Control Structure Offsets for Channel 7 (continued)

Offset	Description
Control Table Base + 0x074	Channel 7 Destination End Pointer
Control Table Base + 0x078	Channel 7 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 9-10.

Table 9-10. Channel Control Word Configuration for Peripheral Transmit Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[7]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

9.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The μ DMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a μ DMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the μ DMA controller disables the channel and sets the `XFERMODE` field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the `XFERMODE` field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral interrupt handler receives an interrupt when the entire transfer is complete.

9.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the μ DMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses μ DMA channel 8.

9.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

9.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the μ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 9-11.

Table 9-11. Primary and Alternate Channel Control Structure Offsets for Channel 8

Offset	Description
Control Table Base + 0x080	Channel 8 Primary Source End Pointer
Control Table Base + 0x084	Channel 8 Primary Destination End Pointer
Control Table Base + 0x088	Channel 8 Primary Control Word
Control Table Base + 0x280	Channel 8 Alternate Source End Pointer
Control Table Base + 0x284	Channel 8 Alternate Destination End Pointer
Control Table Base + 0x288	Channel 8 Alternate Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.

2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 9-12.
2. Program the alternate channel control word at offset 0x288 according to Table 9-12.

Table 9-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[8]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

9.3.4.3 Configure the Peripheral Interrupt

An interrupt handler should be configured when using μ DMA Ping-Pong mode, it is best to use an interrupt handler. However, the Ping-Pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

9.3.4.4 Enable the μ DMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

9.3.4.5 Process Interrupts

The μ DMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the μ DMA request signal, the μ DMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the `XFERMODE` field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:
 - a. Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.
 - b. Reprogram the primary channel control word at offset 0x88 according to Table 9-12 on page 601.
2. Read the alternate channel control word at offset 0x288 and check the `XFERMODE` field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
 - a. Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
 - b. Reprogram the alternate channel control word at offset 0x288 according to Table 9-12 on page 601.

9.3.5 Configuring Channel Assignments

Channel assignments for each μ DMA channel can be changed using the `DMACHMAPn` registers. Each 4-bit field represents a μ DMA channel.

Refer to Table 9-1 on page 583 for channel assignments.

For example, to use UART1 Receive on channel 8, configure the `CH8SEL` bit in the `DMACHMAP1` register to be 0x1.

9.4 Register Map

Table 9-13 on page 603 lists the μ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, that is, the base address is n/a (not applicable). In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See "Channel Configuration" on page 585 and Table 9-3 on page 586 for a description of how the entries in the channel control table are located in memory. The μ DMA register addresses are given as a hexadecimal increment, relative to the μ DMA base address of 0x400F.F000. Note that the μ DMA module clock must be enabled before the registers can be programmed (see page 377). There must be a delay of 3 system clocks after the μ DMA module clock is enabled before any μ DMA module registers are accessed.

Table 9-13. μ DMA Register Map

Offset	Name	Type	Reset	Description	See page
μDMA Channel Control Structure (Offset from Channel Control Table Base)

9.5 μ DMA Channel Control Structure

The μ DMA Channel Control Structure holds the transfer settings for a μ DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 585 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. Each channel has a primary and alternate structure. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

DMA Channel Source Address End Pointer (DMASRCENDP) is part of the Channel Control Structure and is used to specify the source address for a μ DMA transfer.

The μ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the μ DMA controller.

Note: The offset specified is from the base address of the control structure in system memory, not the μ DMA module base address.

DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a
Offset 0x000
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Source Address End Pointer This field points to the last address of the μ DMA transfer source (inclusive). If the source address is not incrementing (the SRCINC field in the DMACHCTL register is 0x3), then this field points at the source location itself (such as a peripheral data register).

Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

DMA Channel Destination Address End Pointer (DMADSTENDP) is part of the Channel Control Structure and is used to specify the destination address for a μ DMA transfer.

Note: The offset specified is from the base address of the control structure in system memory, not the μ DMA module base address.

DMA Channel Destination Address End Pointer (DMADSTENDP)

Base n/a
Offset 0x004
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	<p>Destination Address End Pointer</p> <p>This field points to the last address of the μDMA transfer destination (inclusive). If the destination address is not incrementing (the <code>DSTINC</code> field in the <code>DMACHCTL</code> register is 0x3), then this field points at the destination location itself (such as a peripheral data register).</p>

Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008

DMA Channel Control Word (DMACHCTL) is part of the Channel Control Structure and is used to specify parameters of a μ DMA transfer.

Note: The offset specified is from the base address of the control structure in system memory, not the μ DMA module base address.

DMA Channel Control Word (DMACHCTL)

Base n/a

Offset 0x008

0x3	Ping-Pong																					
0x4	Memory Scatter-Gather																					
0x5	Alternate Memory Scatter-Gather																					
0x6	Peripheral Scatter-Gather																					
0x7	Alternate Peripheral Scatter-Gather																					

XFERMODE Bit Field Values.

Stop

Channel is stopped or configuration data is invalid. No more transfers can occur.

Basic

For each trigger (whether from a peripheral or a software request), the μ DMA controller performs the number of transfers specified by the ARBSIZE field.

Auto-Request

The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of XFERSIZE items without any further requests.

Ping-Pong

This mode uses both the primary and alternate control structures for this channel. When the number of transfers specified by the XFERMODE field have completed for the current control structure (primary or alternate), the μ DMA controller switches to the other one. These switches continue until one of the control structures is not set to ping-pong mode. At that point, the μ DMA controller stops. An interrupt is generated on completion of the transfers configured by each control structure. See “Ping-Pong” on page 587.

Memory Scatter-Gather

When using this mode, the primary control structure for the channel is configured to allow a list of operations (tasks) to be performed. The source address pointer specifies the start of a table of tasks to be copied to the alternate control structure for this channel. The XFERMODE field for the alternate control structure should be configured to 0x5 (Alternate memory scatter-gather) to perform the task. When the task completes, the μ DMA switches back to the primary channel control structure, which then copies the next task to the alternate control structure. This process continues until the table of tasks is empty. The last task must have an XFERMODE value other than 0x5. Note that for continuous operation, the last task can update the primary channel control structure back to the start of the list or to another list. See “Memory Scatter-Gather” on page 589.

Alternate Memory Scatter-Gather

This value must be used in the alternate channel control data structure when the μ DMA controller operates in Memory Scatter-Gather mode.

Peripheral Scatter-Gather

This value must be used in the primary channel control data structure when the μ DMA controller operates in Peripheral Scatter-Gather mode. In this mode, the μ DMA controller operates exactly the same as in Memory Scatter-Gather mode, except that instead of performing the number of transfers specified by the `XFERSIZE` field in the alternate control structure at one time, the μ DMA controller only performs the number of transfers specified by the `ARBSIZE` field per trigger; see Basic mode for details. See “Peripheral Scatter-Gather” on page 592.

Alternate Peripheral Scatter-Gather

This value must be used in the alternate channel control data structure when the μ DMA controller operates in Peripheral Scatter-Gather mode.

9.6 μ DMA Register Descriptions

The register addresses given are relative to the μ DMA base address of 0x400F.F000.

Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the μ DMA controller. You cannot read this register when the μ DMA controller is in the reset state.

DMA Status (DMASTAT)

Base 0x400F.F000

Offset 0x000

Type RO, reset 0x001F.0000

0	MASTEN	WO	-	Controller Master Enable
				Value Description
				0 Disables the μ DMA controller.
				1 Enables μ DMA controller.

Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that must be assigned to the μ DMA controller depends on the number of μ DMA channels used and whether the alternate channel control data structure is used. See “Channel Configuration” on page 585 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. This register cannot be read when the μ DMA controller is in the reset state.

DMA Channel Control Base Pointer (DMACTLBASE)

Base 0x400F.F000
Offset 0x008
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:10	ADDR	R/W	0x0000.00	Channel Control Base Address This field contains the pointer to the base address of the channel control table. The base address must be 1024-byte aligned.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. This register cannot be read when the μ DMA controller is in the reset state.

DMA Alternate Channel Control Base Pointer (DMAALTBASE)

Base 0x400F.F000
 Offset 0x00C
 Type RO, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RO	0x0000.0200	Alternate Channel Address Pointer This field provides the base address of the alternate channel control structures.

Register 8: DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the μ DMA channel is waiting on a request. A peripheral can hold off the μ DMA from performing a single request until the peripheral is ready for a burst request to enhance the μ DMA performance. The use of this feature is dependent on the design of the peripheral and is not controllable by software in any way. This register cannot be read when the μ DMA controller is in the reset state.

DMA Channel Wait-on-Request Status (DMAWAITSTAT)

Base 0x400F.F000

Offset 0x010

Type RO, reset 0xFFFF.FFC0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	WAITREQ[n]	RO	0xFFFF.FFC0	Channel [n] Wait Status These bits provide the channel wait-on-request status. Bit 0 corresponds to channel 0.
				Value Description
				1 The corresponding channel is waiting on a request.
				0 The corresponding channel is not waiting on a request.

Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding μ DMA channel. Setting a bit generates a request for the specified μ DMA channel.

DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	SWREQ[n]	WO	-	<p>Channel [n] Software Request</p> <p>These bits generate software requests. Bit 0 corresponds to channel 0.</p> <p>Value Description</p> <p>1 Generate a software request for the corresponding channel.</p> <p>0 No request generated.</p> <p>These bits are automatically cleared when the software request has been completed.</p>

Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018

Each bit of the **DMAUSEBURSTSET** register represents the corresponding μ DMA channel. Setting a bit disables the channel's single request input from generating requests, configuring the channel to only accept burst requests. Reading the register returns the status of USEBURST.

If the amount of data to transfer is a multiple of the arbitration (burst) size, the corresponding $SET[n]$ bit is cleared after completing the final transfer. If there are fewer items remaining to transfer than the arbitration (burst) size, the μ DMA controller automatically clears the corresponding $SET[n]$ bit, allowing the remaining items to transfer using single requests. In order to resume transfers using burst requests, the corresponding bit must be set again. A bit should not be set if the corresponding peripheral does not support the burst request model.

Refer to “Request Types” on page 585 for more details about request types.

DMA Channel Useburst Set (DMAUSEBURSTSET)

Base 0x400F.F000
Offset 0x018
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SET[n]															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SET[n]															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R/W	0x0000.0000	Channel [n] Useburst Set

Value	Description
0	μ DMA channel [n] responds to single or burst requests.
1	μ DMA channel [n] responds only to burst requests.

Bit 0 corresponds to channel 0. This bit is automatically cleared as described above. A bit can also be manually cleared by setting the corresponding $CLR[n]$ bit in the **DMAUSEBURSTCLR** register.

Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding μ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register.

DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Useburst Clear

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register meaning that μ DMA channel [n] responds to single and burst requests.

Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding μ DMA channel. Setting a bit disables μ DMA requests for the channel. Reading the register returns the request mask status. When a μ DMA channel's request is masked, that means the peripheral can no longer request μ DMA transfers. The channel can then be used for software-initiated transfers.

DMA Channel Request Mask Set (DMAREQMASKSET)

Base 0x400F.F000
Offset 0x020
Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R/W	0x0000.0000	Channel [n] Request Mask Set

Value Description

Value	Description
0	The peripheral associated with channel [n] is enabled to request μ DMA transfers.
1	The peripheral associated with channel [n] is not able to request μ DMA transfers. Channel [n] may be used for software-initiated transfers.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAREQMASKCLR** register.

Register 13: DMA Channel Request Mask Clear (DMAREQMASKCLR), offset 0x024

Each bit of the **DMAREQMASKCLR** register represents the corresponding μ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAREQMASKSET** register.

DMA Channel Request Mask Clear (DMAREQMASKCLR)

Base 0x400F.F000

Offset 0x024

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Request Mask Clear

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAREQMASKSET** register meaning that the peripheral associated with channel [n] is enabled to request μ DMA transfers.

Register 14: DMA Channel Enable Set (DMAENASET), offset 0x028

Each bit of the **DMAENASET** register represents the corresponding μ DMA channel. Setting a bit enables the corresponding μ DMA channel. Reading the register returns the enable status of the channels. If a channel is enabled but the request mask is set (**DMAREQMASKSET**), then the channel can be used for software-initiated transfers.

DMA Channel Enable Set (DMAENASET)

Base 0x400F.F000
Offset 0x028
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R/W	0x0000.0000	Channel [n] Enable Set

Value	Description
0	μ DMA Channel [n] is disabled.
1	μ DMA Channel [n] is enabled.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding **CLR[n]** bit in the **DMAENACL** register.

Register 15: DMA Channel Enable Clear (DMAENACLRL), offset 0x02C

Each bit of the **DMAENACLRL** register represents the corresponding μ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAENASET** register.

DMA Channel Enable Clear (DMAENACLRL)

Base 0x400F.F000

Offset 0x02C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Clear Channel [n] Enable Clear

Value	Description
0	No effect.
1	Setting a bit clears the corresponding SET[n] bit in the DMAENASET register meaning that channel [n] is disabled for μ DMA transfers.

Note: The controller disables a channel when it completes the μ DMA cycle.

Register 16: DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030

Each bit of the **DMAALTSET** register represents the corresponding μ DMA channel. Setting a bit configures the μ DMA channel to use the alternate control data structure. Reading the register returns the status of which control data structure is in use for the corresponding μ DMA channel.

DMA Channel Primary Alternate Set (DMAALTSET)

Base 0x400F.F000
Offset 0x030
Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R/W	0x0000.0000	Channel [n] Alternate Set

Value Description

Value	Description
0	μ DMA channel [n] is using the primary control structure.
1	μ DMA channel [n] is using the alternate control structure.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAALTCLR** register.

Note: For Ping-Pong and Scatter-Gather cycle types, the μ DMA controller automatically sets these bits to select the alternate channel control data structure.

Register 17: DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034

Each bit of the **DMAALTCLR** register represents the corresponding μ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAALTSET** register.

DMA Channel Primary Alternate Clear (DMAALTCLR)

Base 0x400F.F000
 Offset 0x034
 Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Alternate Clear

Value	Description
0	No effect.
1	Setting a bit clears the corresponding SET[n] bit in the DMAALTSET register meaning that channel [n] is using the primary control structure.

Note: For Ping-Pong and Scatter-Gather cycle types, the μ DMA controller automatically sets these bits to select the alternate channel control data structure.

Register 18: DMA Channel Priority Set (DMAPRIOSET), offset 0x038

Each bit of the **DMAPRIOSET** register represents the corresponding μ DMA channel. Setting a bit configures the μ DMA channel to have a high priority level. Reading the register returns the status of the channel priority mask.

DMA Channel Priority Set (DMAPRIOSET)

Base 0x400F.F000
Offset 0x038
Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R/W	0x0000.0000	Channel [n] Priority Set

Value Description

- 0 μ DMA channel [n] is using the default priority level.
- 1 μ DMA channel [n] is using a high priority level.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAPRIOCLR** register.

Register 19: DMA Channel Priority Clear (DMAPRIOCLR), offset 0x03C

Each bit of the **DMAPRIOCLR** register represents the corresponding μ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAPRIOSET** register.

DMA Channel Priority Clear (DMAPRIOCLR)

Base 0x400F.F000

Offset 0x03C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Priority Clear
				Value Description
				0 No effect.
				1 Setting a bit clears the corresponding SET[n] bit in the DMAPRIOSET register meaning that channel [n] is using the default priority level.

Register 20: DMA Bus Error Clear (DMAERRCLR), offset 0x04C

The **DMAERRCLR** register is used to read and clear the μ DMA bus error status. The error status is set if the μ DMA controller encountered a bus error while performing a transfer. If a bus error occurs on a channel, that channel is automatically disabled by the μ DMA controller. The other channels are unaffected.

DMA Bus Error Clear (DMAERRCLR)

Base 0x400F.F000
Offset 0x04C
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	ERRCLR	R/W1C	0	μ DMA Bus Error Status
				Value Description
				0 No bus error is pending.
				1 A bus error is pending.
				This bit is cleared by writing a 1 to it.

Register 21: DMA Channel Assignment (DMACHASGN), offset 0x500

Each bit of the **DMACHASGN** register represents the corresponding μ DMA channel. Setting a bit selects the secondary channel assignment as specified in Table 9-1 on page 583.

Note: This register is provided to support legacy software. New software should use the **DMACHMAPn** registers. If a bit is clear in this register, the corresponding field in the **DMACHMAPn** registers is configured to 0x0. If a bit is set in this register, the corresponding field is configured to 0x1. If this register is read, a bit reads as 0 if the corresponding **DMACHMAPn** register field value is equal to 0, otherwise it reads as 1 if the corresponding **DMACHMAPn** register field value is not equal to 0.

DMA Channel Assignment (DMACHASGN)

Base 0x400F.F000
 Offset 0x500
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CHASGN[n]	R/W	-	Channel [n] Assignment Select
				Value Description
				0 Use the primary channel assignment.
				1 Use the secondary channel assignment.

Register 22: DMA Channel Interrupt Status (DMACHIS), offset 0x504

Each bit of the **DMACHIS** register represents the corresponding μ DMA channel. A bit is set when that μ DMA channel causes a completion interrupt. The bits are cleared by a writing a 1.

DMA Channel Interrupt Status (DMACHIS)

Base 0x400F.F000

Offset 0x504

Type R/W1C, reset 0x0000.0000

Value Description

1 The corresponding μ DMA channel caused an interrupt.

0 The corresponding μ DMA channel has not caused an interrupt.

This bit is cleared by writing a 1 to it.

Register 23: DMA Channel Map Select 0 (DMACHMAP0), offset 0x510

Each 4-bit field of the **DMACHMAP0** register configures the μ DMA channel assignment as specified in Table 9-1 on page 583.

Note: To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, a value of 0x0 is equivalent to a **DMACHASGN** bit being clear, and a value of 0x1 is equivalent to a **DMACHASGN** bit being set.

10 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of six physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F). The GPIO module supports up to 43 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Up to 43 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant in input configuration
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code for Ports A-H and J; Ports K-N and P-Q are accessed through the AHB
- Fast toggle capable of a change every clock cycle for ports on AHB, every two clock cycles for ports on APB
- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
 - Per-pin interrupts available on Port P and Port Q
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a μ DMA transfer
- Pin state can be retained during Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
 - Slew rate control for the 8-mA drive
 - Open drain enables
 - Digital input enables

10.1 Signal Description

GPIO signals have alternate hardware functions. The following table lists the GPIO pins and their analog and digital alternate functions. The A_{INx} analog signals are not 5-V tolerant and go through

an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry (C0-, C0+, C1-, C1+). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. All GPIO signals are 5-V tolerant when configured as inputs except for PB0 and PB1, which are limited to 3.6 V. The digital alternate hardware functions are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMC_x bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Note that each pin must be programmed individually; no type of grouping is implied by the columns in the table. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**), with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

Table 10-1. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	0	1	0	0	0x1
PA[5:2]	SSI0	0	1	0	0	0x1
PB[3:2]	I ² C0	0	1	0	0	0x3
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI, see “Commit Control” on page 652.

Table 10-2. GPIO Pins and Alternate Functions (64LQFP)

a. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 10-13 are not used on this device.

10.2 Functional Description

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 10-1 on page 648 and Figure 10-2 on page 649). The LM4F120B2QR microcontroller contains six ports and thus six of these physical GPIO blocks. Note that not all pins may be implemented on every block. Some GPIO pins can function as I/O signals for the on-chip peripheral modules. For information on which GPIO pins are used for alternate hardware functions, refer to Table 21-5 on page 1160.

Figure 10-1. Digital I/O Pads

Figure 10-2. Analog/Digital I/O Pads

10.2.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

10.2.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 658) is used to configure each individual pin as an input or output. When the data direction bit is cleared, the GPIO is configured as an input, and the corresponding data register bit captures and stores the value on the GPIO port. When the data direction bit is set, the GPIO is configured as an output, and the corresponding data register bit is driven out on the GPIO port.

10.2.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 657) by using bits [9:2] of the address bus as a mask. In this manner, software drivers can modify individual GPIO pins in a single instruction without affecting the state of the other pins. This method is more efficient than the conventional method of performing a read-modify-write operation to set or clear an individual GPIO pin. To implement this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address GPIODATA + 0x098 has the results shown in Figure 10-3, where u indicates that data is unchanged by the write.

Figure 10-3. GPIODATA Write Example

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 10-4.

Figure 10-4. GPIODATA Read Example

10.2.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. These registers are used to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, the external source must hold the level constant for the interrupt to be recognized by the controller.

Three registers define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 659)

- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 660)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 661)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 662).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 663 and page 664). As the name implies, the **GPIOMIS** register only shows interrupt conditions that are allowed to be passed to the interrupt controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the interrupt controller.

Interrupts are cleared by writing a 1 to the appropriate bit of the **GPIO Interrupt Clear (GPIOICR)** register (see page 665).

When programming the interrupt control registers (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**), the interrupts should be masked (**GPIOIM** cleared). Writing any value to an interrupt control register can generate a spurious interrupt if the corresponding bits are enabled.

10.2.2.1 Interrupts Per Pin

Each pin of GPIO PortP and PortQ can capture a system interrupt. Each pin has a dedicated interrupt vector and can be handled by separate interrupt handlers. The **PP0** and **PQ0** interrupts serve as a master interrupt and provide a legacy aggregated interrupt version. For interrupt assignments, see Table 2-9 on page 97.

10.2.2.2 ADC Trigger Source

Any GPIO pin can be configured to be an external trigger for the ADC using the **GPIO ADC Control (GPIOADCCTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), and interrupt for that port is generated, and an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 823.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous Stellaris devices to operate on this microcontroller.

10.2.2.3 μ DMA Trigger Source

Any GPIO pin can be configured to be an external trigger for the μ DMA using the **GPIO DMA Control (GPIODMACTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), an interrupt for that port is generated and an external trigger signal is sent to the μ DMA. If the μ DMA is configured to start a transfer based on the GPIO signal, a transfer is initiated.

10.2.3 Mode Control

The GPIO pins can be controlled by either software or hardware. Software control is the default for most signals and corresponds to the GPIO mode, where the **GPIODATA** register is used to read or write the corresponding pins. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 666), the pin state is controlled by its alternate function (that is, the peripheral).

Further pin muxing options are provided through the **GPIO Port Control (GPIOCTL)** register which selects one of several peripheral functions for each GPIO. For information on the configuration options, refer to Table 21-5 on page 1160.

Note: If any pin is to be used as an ADC input, the appropriate bit in the **GPIOAMSEL** register must be set to disable the analog isolation circuit.

10.2.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins ($PC[3:0]$) and the NMI pin ($PD7$ and $PF0$). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 666), **GPIO Pull Up Select (GPIOPUR)** register (see page 672), **GPIO Pull-Down Select (GPIOPDR)** register (see page 674), and **GPIO Digital Enable (GIODEN)** register (see page 677) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 679) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 680) have been set.

10.2.5 Pad Control

The pad control registers allow software to configure the GPIO pads based on the application requirements. The pad control registers include the **GIODR2R**, **GIODR4R**, **GIODR8R**, **GPIOODR**, **GPIOPUR**, **GPIOPDR**, **GIOSLR**, and **GIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable for each GPIO.

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V_{OL} value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

10.2.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GIOPeriphID7** registers as well as the **GPIOCellID0-GIOPCellID3** registers.

10.3 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHBCTL** register (see page 276). Note that GPIO ports K, L, M, N, P, and Q can only be accessed through the AHB aperture.

To use the pins in a particular GPIO port, the clock for the port must be enabled by setting the appropriate GPIO Port bit field ($GPIO_n$) in the **RCGCGPIO** register (see page 374).

When the internal POR signal is asserted and until otherwise configured, all GPIO pins are configured to be undriven (tristate): **GPIOAFSEL=0**, **GIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**, except for the pins shown in Table 10-1 on page 646. Table 10-3 on page 653 shows all possible configurations

of the GPIO pads and the control register settings required to achieve them. Table 10-4 on page 653 shows how a rising edge interrupt is configured for pin 2 of a GPIO port.

Table 10-3. GPIO Pad Configuration Examples

Configuration	GPIO Register Bit Value ^a									
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	SLR
Digital Input (GPIO)	0	0	0	1	?	?	X	X	X	X

GPIOIEV	0=Low level, or falling edge 1=High level, or rising edge	X	X	X	X	X	1	X	X
GPIOIM	0=masked 1=not masked	0	0	0	0	0	1	0	0

a. X=Ignored (don't care bit)

10.4 Register Map

Table 10-6 on page 655 lists the GPIO registers. Each GPIO port can be accessed through one of two bus apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus.

Important: The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to unconnected bits has no effect, and reading unconnected bits returns no meaningful data.

The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (APB): 0x4000.4000
- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (APB): 0x4000.5000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (APB): 0x4000.6000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (APB): 0x4000.7000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (APB): 0x4002.4000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (APB): 0x4002.5000
- GPIO Port F (AHB): 0x4005.D000

Note that each GPIO module clock must be enabled before the registers can be programmed (see page 374). There must be a delay of 3 system clocks after the GPIO module clock is enabled before any GPIO module registers are accessed.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIOIDEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0, with the exception of the pins shown in the table below. A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts the pins back to their default state.

Table 10-5. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIOIDEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	0	1	0	0	0x1
PA[5:2]	SSI0	0	1	0	0	0x1
PB[3:2]	I ² C0	0	1	0	0	0x3
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI, see "Commit Control" on page 652.

The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins ($PD7$, $PF0$, and $PC[3:0]$). These six pins are the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port D7, GPIO Port F0, and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins ($PD7$, $PF0$, and $PC[3:0]$). To ensure that the JTAG port is not accidentally programmed as GPIO pins, the $PC[3:0]$ pins default to non-committable. Similarly, to ensure that the NMI pin is not accidentally programmed as a GPIO pin, the $PD7$ and

PF0 pins default to non-committable. Because of this, the default reset value of **GPIOCR** for GPIO Port C is 0x0000.00F0, for GPIO Port D is 0x0000.007F, and for GPIO Port F is 0x0000.00FE.

Table 10-6. GPIO Register Map

Offset	Name	Type	Reset	Description	See page
0x000	GPIODATA	R/W	0x0000.0000	GPIO Data	657
0x400	GPIODIR	R/W	0x0000.0000	GPIO Direction	658
0x404	GPIOIS	R/W	0x0000.0000	GPIO Interrupt Sense	659
0x408	GPIOIBE	R/W	0x0000.0000	GPIO Interrupt Both Edges	660
0x40C	GPIOIEV	R/W	0x0000.0000	GPIO Interrupt Event	661
0x410	GPIOIM	R/W	0x0000.0000	GPIO Interrupt Mask	662
0x414	GPIORIS	RO	0x0000.0000	GPIO Raw Interrupt Status	663
0x418	GPIONIS	RO	0x0000.0000	GPIO Masked Interrupt Status	664
0x41C	GPIOICR	W1C	0x0000.0000	GPIO Interrupt Clear	665
0x420	GPIOAFSEL	R/W	-	GPIO Alternate Function Select	666
0x500	GPIODR2R	R/W	0x0000.00FF	GPIO 2-mA Drive Select	668
0x504	GPIODR4R	R/W	0x0000.0000	GPIO 4-mA Drive Select	669
0x508	GPIODR8R	R/W	0x0000.0000	GPIO 8-mA Drive Select	670

10.5 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 658).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be set. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are set in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are clear in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

GPIO Data (GPIODATA)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (APB) base: 0x4000.6000
 GPIO Port C (AHB) base: 0x4005.A000
 GPIO Port D (APB) base: 0x4000.7000
 GPIO Port D (AHB) base: 0x4005.B000
 GPIO Port E (APB) base: 0x4002.4000
 GPIO Port E (AHB) base: 0x4005.C000
 GPIO Port F (APB) base: 0x4002.5000
 GPIO Port F (AHB) base: 0x4005.D000
 Offset 0x000
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	GPIO Data This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs. See "Data Register Operation" on page 650 for examples of reads and writes.

Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Setting a bit in the **GPIODIR** register configures the corresponding pin to be an output, while clearing a bit configures the corresponding pin to be an input. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

GPIO Direction (GPIODIR)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (APB) base: 0x4000.6000

31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DIR	R/W	0x00	GPIO Data Direction
				Value Description
				0 Corresponding pin is an input.
				1 Corresponding pins is an output.

Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Setting a bit in the **GPIOIS** register configures the corresponding pin to detect levels, while clearing a bit configures the corresponding pin to detect edges. All bits are cleared by a reset.

GPIO Interrupt Sense (GPIOIS)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (APB) base: 0x4000.6000
 GPIO Port C (AHB) base: 0x4005.A000
 GPIO Port D (APB) base: 0x4000.7000
 GPIO Port D (AHB) base: 0x4005.B000
 GPIO Port E (APB) base: 0x4002.4000
 GPIO Port E (AHB) base: 0x4005.C000
 GPIO Port F (APB) base: 0x4002.5000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IS	R/W	0x00	GPIO Interrupt Sense
				Value Description
				0 The edge on the corresponding pin is detected (edge-sensitive).
				1 The level on the corresponding pin is detected (level-sensitive).

Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register allows both edges to cause interrupts. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 659) is set to detect edges, setting a bit in the **GPIOIBE** register configures the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 661). Clearing a bit configures the pin to be controlled by the **GPIOIEV** register. All bits are cleared by a reset.

GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IBE	R/W	0x00	GPIO Interrupt Both Edges
				Value Description
			0	Interrupt generation is controlled by the GPIO Interrupt Event (GPIOIEV) register (see page 661).
			1	Both edges on the corresponding pin trigger an interrupt.

Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Setting a bit in the **GPIOIEV** register configures the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 659). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in the **GPIOIS** register. All bits are cleared by a reset.

GPIO Interrupt Event (GPIOIEV)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (APB) base: 0x4000.6000
 GPIO Port C (AHB) base: 0x4005.A000
 GPIO Port D (APB) base: 0x4000.7000
 GPIO Port D (AHB) base: 0x4005.B000
 GPIO Port E (APB) base: 0x4002.4000
 GPIO Port E (AHB) base: 0x4005.C000
 GPIO Port F (APB) base: 0x4002.5000
 GPIO Port F (AHB) base: 0x4005.D000
 Offset 0x40C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IEV	R/W	0x00	GPIO Interrupt Event
				Value Description
				0 A falling edge or a Low level on the corresponding pin triggers an interrupt.
				1 A rising edge or a High level on the corresponding pin triggers an interrupt.

Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Setting a bit in the **GPIOIM** register allows interrupts that are generated by the corresponding pin to be sent to the interrupt controller on the combined interrupt signal. Clearing a bit prevents an interrupt on the corresponding pin from being sent to the interrupt controller. All bits are cleared by a reset.

GPIO Interrupt Mask (GPIOIM)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000

7:0	IME	R/W	0x00	GPIO Interrupt Mask Enable

Value Description

Value	Description
0	The interrupt from the corresponding pin is masked.
1	The interrupt from the corresponding pin is sent to the interrupt controller.

Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. A bit in this register is set when an interrupt condition occurs on the corresponding GPIO pin. If the corresponding bit in the **GPIO Interrupt Mask (GPIOIM)** register (see page 662) is set, the interrupt is sent to the interrupt controller. Bits read as zero indicate that corresponding input pins have not initiated an interrupt. A bit in this register can be cleared by writing a 1 to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register.

GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (APB) base: 0x4000.6000
 GPIO Port C (AHB) base: 0x4005.A000
 GPIO Port D (APB) base: 0x4000.7000
 GPIO Port D (AHB) base: 0x4005.B000
 GPIO Port E (APB) base: 0x4002.4000
 GPIO Port E (AHB) base: 0x4005.C000
 GPIO Port F (APB) base: 0x4002.5000
 GPIO Port F (AHB) base: 0x4005.D000
 Offset 0x414

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIS	RO	0x00	GPIO Interrupt Raw Status

Value Description

1	An interrupt condition has occurred on the corresponding pin.
0	An interrupt condition has not occurred on the corresponding pin.

A bit is cleared by writing a 1 to the corresponding bit in the **GPIOICR** register.

Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. If a bit is set in this register, the corresponding interrupt has triggered an interrupt to the interrupt controller. If a bit is clear, either no interrupt has been generated, or the interrupt is masked.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous Stellaris devices to operate on this microcontroller.

GPIOMIS is the state of the interrupt after masking.

GPIO Masked Interrupt Status (GPIOMIS)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000

				Value Description
				1 The corresponding interrupt is cleared.
				0 The corresponding interrupt is unaffected.

Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

The **GPIOAFSEL** register is the mode control select register. If a bit is clear, the pin is used as a GPIO and is controlled by the GPIO registers. Setting a bit in this register configures the corresponding GPIO line to be controlled by an associated peripheral. Several possible peripheral functions are multiplexed on each GPIO. The **GPIO Port Control (GPIOPCTL)** register is used to select one of the possible functions. Table 21-5 on page 1160 details which functions are muxed on each GPIO pin. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**, with the exception of the pins shown in the table below. A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts the pins back to their default state.

Table 10-7. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	0	1	0	0	0x1
PA[5:2]	SSI0	0	1	0	0	0x1
PB[3:2]	I ² C0	0	1	0	0	0x3
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI, see “Commit Control” on page 652.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins ($PC[3:0]$) and the NMI pin ($PD7$ and $PF0$). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 666), **GPIO Pull Up Select (GPIOPUR)** register (see page 672), **GPIO Pull-Down Select (GPIOPDR)** register (see page 674), and **GPIO Digital Enable (GPIODEN)** register (see page 677) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 679) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 680) have been set.

When using the I²C module, in addition to setting the **GPIOAFSEL** register bits for the I²C clock and data pins, the pins should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register (see examples in “Initialization and Configuration” on page 652).

Value Description

- | | |
|---|---|
| 0 | The associated pin functions as a GPIO and is controlled by the GPIO registers. |
| 1 | The associated pin functions as a peripheral signal and is controlled by the alternate hardware function. |
- The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 646.

Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV2** bit for a GPIO signal, the corresponding **DRV4** bit in the **GPIODR4R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware. By default, all GPIO pins have 2-mA drive.

7:0	DRV2	R/W	0xFF	Output Pad 2-mA Drive Enable

Value	Description
1	The corresponding GPIO pin has 2-mA drive.
0	The drive for the corresponding GPIO pin is controlled by the GPIODR4R or GPIODR8R register.

Setting a bit in either the **GPIODR4** register or the **GPIODR8** register clears the corresponding 2-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV4** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware.

7:0	DRV4	R/W	0x00	Output Pad 4-mA Drive Enable

Value Description

1	The corresponding GPIO pin has 4-mA drive.
0	The drive for the corresponding GPIO pin is controlled by the GPIODR2R or GPIODR8R register.

Setting a bit in either the **GPIODR2** register or the **GPIODR8** register clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV8** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV4** bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

Note: There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the V_{OH}/V_{OL} levels. See “Recommended Operating Conditions” on page 1167 for further information.

7:0	DRV8	R/W	0x00	Output Pad 8-mA Drive Enable

Value	Description
1	The corresponding GPIO pin has 8-mA drive.
0	The drive for the corresponding GPIO pin is controlled by the GPIODR2R or GPIODR4R register.

Setting a bit in either the **GPIODR2** register or the **GPIODR4** register clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

Register 14: GPIO Open Drain Select (GPIODR), offset 0x50C

The **GPIODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Enable (GPIODEN)** register (see page 677). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I²C module, in addition to configuring the pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I²C data pins should be set (see examples in “Initialization and Configuration” on page 652).

	Value	Description		
	1	The corresponding pin is configured as open drain.		
	0	The corresponding pin is not configured as open drain.		

Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 674). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0, with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) or asserting **RST** puts the pins back to their default state.

Table 10-8. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	0	1	0	0	0x1

7:0	PUE	R/W	-	Pad Weak Pull-Up Enable

Value Description

- | | |
|---|--|
| 1 | The corresponding pin has a weak pull-up resistor. |
| 0 | The corresponding pin is not affected. |

Setting a bit in the **GPIOPDR** register clears the corresponding bit in the **GPIOPUR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 646.

Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514

The **GPIOPDR** register is the pull-down control register. When a bit is set, a weak pull-down resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 672).

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOCTL**=0, with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) or asserting **RST** puts the pins back to their default state.

Table 10-9. GPIO Pins With Non-Zero Reset Values

31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PDE	R/W	0x00	Pad Weak Pull-Down Enable

Value Description

1	The corresponding pin has a weak pull-down resistor.
0	The corresponding pin is not affected.

Setting a bit in the **GPIOPUR** register clears the corresponding bit in the **GPIOPDR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA drive strength option via the **GPIO 8-mA Drive Select (GPIODR8R)** register (see page 670).

GPIO Slew Rate Control Select (GPIOSLR)

31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.	
7:0	SRL	R/W	0x00	Slew Rate Limit Enable (8-mA drive only)	
Value Description					
	1	Slew rate control is enabled for the corresponding pin.			
	0	Slew rate control is disabled for the corresponding pin.			

Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

Note: Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, all GPIO signals except those listed below are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin as a digital input or output (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0, with the exception of the pins shown in the table below. A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts the pins back to their default state.

Table 10-10. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	0	1	0	0	0x1
PA[5:2]	SSI0	0	1	0	0	0x1
PB[3:2]	I ² C0	0	1	0	0	0x3
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI, see “Commit Control” on page 652.

Note: The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins ($PC[3:0]$) and the NMI pin ($PD7$ and $PF0$). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 666), **GPIO Pull Up Select (GPIOPUR)** register (see page 672), **GPIO Pull-Down Select (GPIOPDR)** register (see page 674), and **GPIO Digital Enable (GPIODEN)** register (see page 677) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 679) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 680) have been set.

GPIO Digital Enable (GPIODEN)

GPIO Port A (APB) base: 0x4000.4000
 GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (APB) base: 0x4000.5000
 GPIO Port B (AHB) base: 0x4005.9000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DEN	R/W	-	Digital Enable

Value	Description
0	The digital functions for the corresponding pin are disabled.
1	The digital functions for the corresponding pin are enabled.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 646.

Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 680). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

Value	Description									
0x1	The GPIOCR register is locked and may not be modified.									
0x0	The GPIOCR register is unlocked and may be modified.									

Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GPIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

Important: This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for PD7, PF0, and PC[3:0], the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins on PD7, PF0, and PC[3:0], all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** register bits of these other pins.

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
7:0	CR	-	-	GPIO Commit
				Value Description
				1 The corresponding GPIODEN , GPIOPUR , GPIOPDR , or GPIODEN bits can be written.
				0 The corresponding GPIODEN , GPIOPUR , GPIOPDR , or GPIODEN bits cannot be written.
				Note: The default register type for the GPIOCR register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins (PD7 , PF0 , and PC[3:0]). These six pins are the only GPIOs that are protected by the GPIOCR register. Because of this, the register type for GPIO Port D7, GPIO Port F0, and GPIO Port C[3:0] is R/W.
				The default reset value for the GPIOCR register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins (PD7 , PF0 , and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as GPIO pins, the PC[3:0] pins default to non-committable. Similarly, to ensure that the NMI pin is not accidentally programmed as a GPIO pin, the PD7 and PF0 pins default to non-committable. Because of this, the default reset value of GPIOCR for GPIO Port C is 0x0000.00F0, for GPIO Port D is 0x0000.007F, and for GPIO Port F is 0x0000.00FE.

Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

Important: This register is only valid for ports and pins that can be used as ADC AINx inputs.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 21-5 on page 1160.

GPIO Analog Mode Select (GPIOAMSEL)

GPIO Port A (APB) base: 0x4000.4000

3:0	GPIOAMSEL	R/W	0x0	GPIO Analog Mode Select

Value	Description
1	The analog function of the pin is enabled, the isolation is disabled, and the pin is capable of analog functions.
0	The analog function of the pin is disabled, the isolation is enabled, and the pin is capable of digital functions as specified by the other GPIO configuration registers.

Note: This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad.

The reset state of this register is 0 for all signals.

Register 22: GPIO Port Control (GPIOCTL), offset 0x52C

The **GPIOCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared on reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the defined encodings for the bit fields in this register, refer to Table 21-5 on page 1160. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOCTL**=0, with the exception of the pins shown in the table below. A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts the pins back to their default state.

Table 10-11. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GIODEN	GPIOPDR	GPIOPUR	GPIOCTL
PA[1:0]	UART0	0	1	0	0	0x1
PA[5:2]	SSI0	0	1	0	0	0x1
PB[3:2]	I ² C0	0	1	0	0	0x3
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI, see “Commit Control” on page 652.

Register 23: GPIO ADC Control (GPIOADCCTL), offset 0x530

This register is used to configure a GPIO pin as a source for the ADC trigger.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous Stellaris devices to operate on this microcontroller.

11 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris® General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Each 32/64-bit Wide GPTM block provides 32-bit timers for Timer A and Timer B that can be concatenated to operate as a 64-bit timer. Timers can also be used to trigger μ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Stellaris microcontrollers. Other timer resources include the System Timer (SysTick) (see 117).

The General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks with the following functional options:

- 16/32-bit operating modes:
 - 16- or 32-bit programmable one-shot timer
 - 16- or 32-bit programmable periodic timer
 - 16-bit general-purpose timer with an 8-bit prescaler
 - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
 - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- 32/64-bit operating modes:
 - 32- or 64-bit programmable one-shot timer
 - 32- or 64-bit programmable periodic timer
 - 32-bit general-purpose timer with a 16-bit prescaler
 - 64-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 32-bit input-edge count- or time-capture modes with a 16-bit prescaler
 - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Twelve 32/64-bit Capture Compare PWM pins (CCP)

- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
 - Dedicated channel for each timer
 - Burst request generated on timer interrupt

11.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the Stellaris device. See Table 11-1 on page 701 for the available CCP pins and their timer assignments.

11.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOCTL)** register (page 683) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 11-2. Signals for General-Purpose Timers (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description

WT1CCP1	13	PC7 (7)	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 1.
WT2CCP0	61	PD0 (7)	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 0.
WT2CCP1	62	PD1 (7)	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 1.
WT3CCP0	63	PD2 (7)	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 0.
WT3CCP1	64	PD3 (7)	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 1.
WT4CCP0	43	PD4 (7)	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.
WT4CCP1	44	PD5 (7)	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.
WT5CCP0	53	PD6 (7)	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 0.
WT5CCP1	10	PD7 (7)	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 1.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

11.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks and a 32-bit counting range for 32/64-bit Wide GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks and a 64-bit counting range for the 32/64-bit Wide GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 11-3 on page 704. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

Table 11-3. General-Purpose Timer Capabilities

Mode	Timer Use	Count Direction	Counter Size		Prescaler Size ^a		Prescaler Behavior (Count Direction)
			16/32-bit GPTM	32/64-bit Wide GPTM	16/32-bit GPTM	32/64-bit Wide GPTM	
One-shot	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Up), Prescaler (Down)
	Concatenated	Up or Down	32-bit	64-bit	-	-	N/A
Periodic	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Up), Prescaler (Down)
	Concatenated	Up or Down	32-bit	64-bit	-	-	N/A
RTC	Concatenated	Up	32-bit	64-bit	-	-	N/A
Edge Count	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Both)
Edge Time	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Both)
PWM	Individual	Down	16-bit	32-bit	8-bit	16-bit	Timer Extension

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 722), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 724), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 728). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

11.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding load registers: the **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 750) and the **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 751) and shadow registers: the **GPTM Timer A Value (GPTMTAV)** register (see page 760) and the **GPTM Timer B Value (GPTMTBV)** register (see page 761). The prescale counters are initialized to 0x00: the **GPTM Timer A Prescale (GPTMTAPR)** register (see page 754), the **GPTM Timer B Prescale (GPTMTBPR)** register (see page 755), the **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 763), the **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 764), the **GPTM Timer A Prescale Value (GPTMTAPV)** register (see page 765), and the **GPTM Timer B Prescale Value (GPTMTBPV)** register (see page 766).

11.3.2 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 722). In the following sections, the variable "n" is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers.

11.3.2.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the $TnMR$ field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 724). The timer is configured to count up or down using the $TnCDIR$ bit in the **GPTMTnMR** register.

When software sets the $TnEN$ bit in the **GPTM Control (GPTMCTL)** register (see page 732), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the $TnWOT$ bit is set in the **GPTMTnMR** register, once the $TnEN$ bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 713).

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional **GPTMTnPR** registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the $TnEN$ bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle. In periodic, snap-shot mode ($TnMR$ field is 0x2 and the $TnSNAPS$ bit is set in the **GPTMTnMR** register), the actual free-running value of the timer at the time-out event is loaded into the **GPTMTnR** register and the free-running value of the prescaler is loaded into the **GPTMTnPS** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer, which is stored in the **GPTMTnV** register. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the time-out event. The GPTM sets the $TnTORIS$ bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 742), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 748). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 739), the GPTM also sets the $TnTOMIS$ bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 745). By setting the $TnMIE$ bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via $TnMRIS$ bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the $TnMIE$ bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the $TnOTE$ bit in **GPTMCTL**. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel. See “Channel Configuration” on page 585.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the $TnILD$ bit in the **GPTMTnMR** register is clear. If the $TnILD$ bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** register while the counter is counting, the match registers reflect the new values on the next clock cycle if the $TnMRSU$ bit in the **GPTMTnMR** register is clear. If the $TnMRSU$ bit is set, the new value don't take effect until the next timeout.

When using a 32/64-bit wide timer block in a 64-bit mode, certain registers must be accessed in the manner described in “Accessing Concatenated 32/64-Bit Wide GPTM Register Values” on page 715.

If the T_{nSTALL} bit in the **GPTMCTL** register is set, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume an 80-MHz clock with $T_c=12.5$ ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode and when a 32/64-bit timer is configured in 32-bit mode.

Table 11-4. 16-Bit Timer With Prescaler Configurations

Prescale (8-bit value)	# of Timer Clocks (T_c) ^a	Max Time	Units
00000000	1	0.8192	ms
00000001	2	1.6384	ms
00000010	3	2.4576	ms
-----	--	--	--
11111101	254	208.0768	ms
11111110	255	208.896	ms
11111111	256	209.7152	ms

a. T_c is the clock period.

The following table shows a variety of configurations for a 32-bit free-running timer using the prescaler while configured in 32/64-bit mode. All values assume an 80-MHz clock with $T_c=12.5$ ns (clock period).

Table 11-5. 32-Bit Timer (configured in 32/64-bit mode) With Prescaler Configurations

Prescale (16-bit value)	# of Timer Clocks (T_c) ^a	Max Time	Units
0x0000	1	53.687	s
0x0001	2	107.374	s
0x0002	3	214.748	s
-----	--	--	--
0xFFFFD	65534	0.879	10^6 s
0xFFFFE	65535	1.759	10^6 s
0xFFFFF	65536	3.518	10^6 s

a. T_c is the clock period.

11.3.2.2 Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 750).

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the $TAEN$ bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the RTC_{CRIS} bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the $TAEN$ bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the

RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

When using a 32/64-bit wide timer block in a RTC mode, certain registers must be accessed in the manner described in “Accessing Concatenated 32/64-Bit Wide GPTM Register Values” on page 715.

The value of the RTC predivider can be read in the **GPTM RTC Predivide (GPTMRTCPD)** register. To ensure that the RTC value is coherent, software should follow the process detailed in Figure 11-2 on page 707.

Figure 11-2. Reading the RTC Value

In addition to generating interrupts, a μ DMA trigger can be generated. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel. See “Channel Configuration” on page 585.

If the **TASTALL** bit in the **GPTMCTL** register is set, the timer does not freeze when the processor is halted by the debugger if the **RTCEN** bit is set in **GPTMCTL**.

11.3.2.3 Input Edge-Count Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low

for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Count mode, the timer is configured as a 24-bit or 48-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the **TnCMR** bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the **TnEVENT** fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHHR** and **GPTMTnPMR** registers.

When software writes the **TnEN** bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the **CnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnMMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register.

In addition to generating interrupts, an ADC and/or a μ DMA trigger can be generated. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL**. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel. See “Channel Configuration” on page 585.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the **TnEN** bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until **TnEN** is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 11-3 on page 709 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the **TnEN** bit after the current count matches the value in the **GPTMTnMATCHHR** register.

Figure 11-3. Input Edge-Count Mode Example, Counting Down

11.3.2.4 Input Edge-Time Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit or 48-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCTL** register.

When software writes the **TnEN** bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** registers and is available to be read by the microcontroller. The GPTM then asserts the **CnERIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. The **GPTMTnV** and the **GPTMTnPV** contain the free-running value of the timer and can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, an ADC and/or a μ DMA trigger can be generated. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL**. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel. See “Channel Configuration” on page 585.

After an event has been captured, the timer does not stop counting. It continues to count until the **TnEN** bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 11-4 on page 710 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

Figure 11-4. 16-Bit Input Edge-Time Mode Example

11.3.2.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit or 48-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x1 or 0x2.

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 713). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the **TnEVENT** field of the **GPTMCTL** register, and the interrupt is enabled by setting the **TnPWMIE** bit in the **GPTMTnMR** register. When the event occurs, the **CnERIS** bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the **TnPWMIE** bit is set.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the

GPTMTnMATCHR and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

Figure 11-5 on page 711 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR** = 0xC350 and the match value is **GPTMTnMATCHR** = 0x411A.

Figure 11-5. 16-Bit PWM Mode Example

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the **PLO** and the **MRSU** bits must be set in the **GPTMTnMR** register. Figure 11-6 on page 712 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is greater than the **GPTMTnILR** value.

Figure 11-6. CCP Output, GPTMTnMATCHR > GPTMTnILR

Figure 11-7 on page 712 shows how the CCP output operates when the `PLO` and `MRSU` bits are set and the **GPTMTnMATCHR** value is the same as the **GPTMTnILR** value.

Figure 11-7. CCP Output, GPTMTnMATCHR = GPTMTnILR

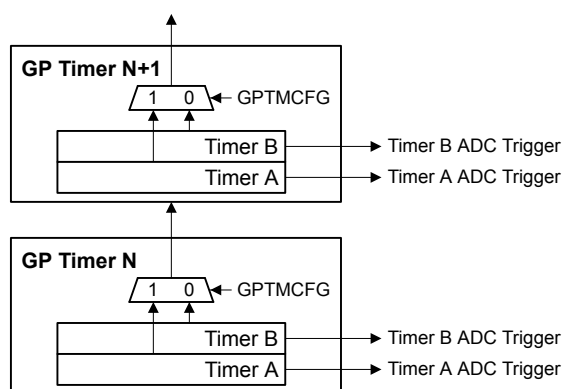

Figure 11-8 on page 713 shows how the CCP output operates when the `PLO` and `MRSU` bits are set and the **GPTMTnILR** is greater than the **GPTMTnMATCHR** value.

Figure 11-8. CCP Output, GPTMnILR > GPTMnMATCHR

11.3.3 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the T_{nWOT} bit in the **GPTMnMR** register. When the T_{nWOT} bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) or 64-bit (32/64-bit wide mode) timer (controlled by the **GPTMCFG** field in the **GPTMCFG** register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) or 32-bit (32/64-bit wide mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Care must be taken that the T_{AWOT} bit is never set in GPTM0. Figure 11-9 on page 713 shows how the **GPTMCFG** bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

Figure 11-9. Timer Daisy Chain

11.3.4 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected Timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated Timer to perform the actions of a timeout event. An interrupt is not

generated when the Timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

Table 11-6 on page 714 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

Table 11-6. Timeout Actions for GPTM Modes

Mode	Count Dir	Time Out Action
32- and 64-bit One-Shot (concatenated timers)	—	N/A
32- and 64-bit Periodic (concatenated timers)	Down	Count value = ILR
	Up	Count value = 0
32- and 64-bit RTC (concatenated timers)	Up	Count value = 0
16- and 32-bit One Shot (individual/split timers)	—	N/A
16- and 32-bit Periodic (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16- and 32-bit Edge-Count (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16- and 32-bit Edge-Time (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16- and 32-bit PWM	Down	Count value = ILR

11.3.5 DMA Operation

The timers each have a dedicated μ DMA channel and can provide a request signal to the μ DMA controller. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the μ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the μ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the μ DMA controller transfers 8 items, until all 256 items have been transferred.

No other special steps are needed to enable Timers for μ DMA operation. Refer to “Micro Direct Memory Access (μ DMA)” on page 581 for more details about programming the μ DMA controller.

11.3.6 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the **GPTMCFG** bit field in the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR)** register [15:0], see page 750
- **GPTM Timer B Interval Load (GPTMTBILR)** register [15:0], see page 751
- **GPTM Timer A (GPTMTAR)** register [15:0], see page 758
- **GPTM Timer B (GPTMTBR)** register [15:0], see page 759

- **GPTM Timer A Value (GPTMTAV)** register [15:0], see page 760
- **GPTM Timer B Value (GPTMTBV)** register [15:0], see page 761
- **GPTM Timer A Match (GPTMTAMATCHR)** register [15:0], see page 752
- **GPTM Timer B Match (GPTMTBMATCHR)** register [15:0], see page 753

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

A 32-bit read access to **GPTMTAV** returns the value:

```
GPTMTBV[15:0]:GPTMTAV[15:0]
```

11.3.7 Accessing Concatenated 32/64-Bit Wide GPTM Register Values

On the 32/64-bit Wide GPTM blocks, concatenated register values (64-bits and 48-bits) are not readily available as the bit width for these accesses is greater than the bus width of the processor core. In the concatenated timer modes and the individual timer modes when using the prescaler, software must perform atomic accesses for the value to be coherent. When reading timer values that are greater than 32 bits, software should follow these steps:

1. Read the appropriate Timer B register or prescaler register.
2. Read the corresponding Timer A register.
3. Re-read the Timer B register or prescaler register.
4. Compare the Timer B or prescaler values from the first and second reads. If they are the same, the timer value is coherent. If they are not the same, repeat steps 1-4 once more so that they are the same.

The following pseudo code illustrates this process:

```
high = timer_high;

low = timer_low;

if (high != timer_high); //low overflowed into high
{
    high = timer_high;
    low = timer_low;
}
```

The registers that must be read in this manner are shown below:

- 64-bit reads
 - **GPTMTAV** and **GPTMTBV**
 - **GPTMTAR** and **GPTMTBR**
- 48-bit reads
 - **GPTMTAR** and **GPTMTAPS**
 - **GPTMTBR** and **GPTMTBPS**
 - **GPTMTAV** and **GPTMTAPV**
 - **GPTMTBV** and **GPTMTBPV**

Similarly, write accesses must also be performed by writing the upper bits prior to writing the lower bits as follows:

1. Write the appropriate Timer B register or prescaler register.
2. Write the corresponding Timer A register.

The registers that must be written in this manner are shown below:

- 64-bit writes
 - **GPTMTAV** and **GPTMTBV**
 - **GPTMTAMATCHR** and **GPTMTBMATCHR**
 - **GPTMTAILR** and **GPTMTBILR**
- 48-bit writes
 - **GPTMTAV** and **GPTMTAPV**
 - **GPTMTBV** and **GPTMTBPV**
 - **GPTMTAMATCHR** and **GPTMTAPMR**
 - **GPTMTBMATCHR** and **GPTMTBPMR**
 - **GPTMTAILR** and **GPTMTAPR**
 - **GPTMTBILR** and **GPTMTBPR**

When writing a 64-bit value, if there are two consecutive writes to any of the registers listed above under the "64-bit writes" heading, whether the register is in Timer A or Timer B, or if a register in Timer A is written prior to writing the corresponding register in Timer B, then an error is reported using the **WUERIS** bit in the **GPTMRIS** register. This error can be promoted to interrupt if it is not masked. Note that this error is not reported for the prescaler registers because use of the prescaler is optional. As a result, programmers must take care to follow the protocol outlined above.

11.4 Initialization and Configuration

To use a GPTM, the appropriate `TIMERN` bit must be set in the `RCGCTIMER` or `RCGCWTIMER` register (see page 372 and page 390). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the `RCGCGPIO` register (see page 374). To find out which GPIO port to enable, refer to Table 21-4 on page 1156. Configure the `PMCn` fields in the `GPIOPCTL` register to assign the CCP signals to the appropriate pins (see page 683 and Table 21-5 on page 1160).

This section shows module initialization and configuration examples for each of the supported timer modes.

11.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit in the `GPTMCTL` register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of `0x0000.0000`.
3. Configure the `TnMR` field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
 - a. Write a value of `0x1` for One-Shot mode.
 - b. Write a value of `0x2` for Periodic mode.
4. Optionally configure the `TnSNAPS`, `TnWOT`, `TnMTE`, and `TnCDIR` bits in the `GPTMTnMR` register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TnEN` bit in the `GPTMCTL` register to enable the timer and start counting.
8. Poll the `GPTMRIS` register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the `TnMIE` bit in the `GPTMTnMR` register is set, the `RTCRES` bit in the `GPTMRIS` register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

11.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of `0x0000.0001`.
3. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.

4. Set/clear the `RTCEN` bit in the **GPTM Control Register (GPTMCTL)** as needed.
5. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the `RTCRES` bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the `RTCCINT` bit in the **GPTMICR** register.

11.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of `0x0000.0004`.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to `0x0` and the `TnMR` field to `0x3`.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. Load the event count into the **GPTM Timer n Match (GPTMTnMATCHR)** register.
8. If interrupts are required, set the `CnMIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
9. Set the `TnEN` bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
10. Poll the `CnMRIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnMCINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the `TnEN` bit is cleared and repeat step 4 on page 718 through step 9 on page 718.

11.4.4 Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of `0x0000.0004`.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to `0x1` and the `TnMR` field to `0x3`.
4. Configure the type of event that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.

5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the **CnEIM** bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the **TnEN** bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the **CnERIS** bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the **CnECINT** bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

11.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the **TnPWML** field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the **TnEVENT** field in the **GPTMCTL** register and enable the interrupts by setting the **TnPWMIE** bit in the **GPTMTnMR** register.
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the **TnEN** bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

11.5 Register Map

Table 11-7 on page 720 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000

- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 32/64-bit Wide Timer 0: 0x4003.6000
- 32/64-bit Wide Timer 1: 0x4003.7000
- 32/64-bit Wide Timer 2: 0x4004.C000
- 32/64-bit Wide Timer 3: 0x4004.D000
- 32/64-bit Wide Timer 4: 0x4004.E000
- 32/64-bit Wide Timer 5: 0x4004.F000

The `SIZE` field in the **GPTM Peripheral Properties (GPTMPP)** register identifies whether a module has a 16/32-bit or 32/64-bit wide timer.

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 372 or page 390). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

11.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 64-bit mode (concatenated timers) or in 16- or 32-bit mode (individual, split timers).

Important: Bits in this register should only be changed when the TAEN and TBEN bits in the GPTMCTL register are cleared.

GPTM Configuration (GPTMCFG)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 32/64-bit Wide Timer 0 base: 0x4003.6000
 32/64-bit Wide Timer 1 base: 0x4003.7000
 32/64-bit Wide Timer 2 base: 0x4004.C000
 32/64-bit Wide Timer 3 base: 0x4004.D000
 32/64-bit Wide Timer 4 base: 0x4004.E000
 32/64-bit Wide Timer 5 base: 0x4004.F000

Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TAAMS** bit, clear the **TACMR** bit, and configure the **TAMR** field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

Important: Bits in this register should only be changed when the **TAEN** bit in the **GPTMCTL** register is cleared.

GPTM Timer A Mode (GPTMTAMR)

11	TAPLO	R/W	0	GPTM Timer A PWM Legacy Operation
				Value Description
			0	Legacy operation with CCP pin cleared to 0 on timeout.
			1	CCP is set to 1 on timeout..
				This bit is only valid in PWM mode.

Bit/Field	Name	Type	Reset	Description
10	TAMRSU	R/W	0	<p>GPTM Timer A Match Register Update</p> <p>Value Description</p> <p>0 Update the GPTMTAMATCHR register and the GPTMTAPR register, if used, on the next cycle.</p> <p>1 Update the GPTMTAMATCHR register and the GPTMTAPR register, if used, on the next timeout.</p> <p>If the timer is disabled (TAEN is clear) when this bit is set, GPTMTAMATCHR and GPTMTAPR are updated when the timer is enabled. If the timer is stalled (TASTALL is set), GPTMTAMATCHR and GPTMTAPR are updated according to the configuration of this bit.</p>
9	TAPWMIE	R/W	0	<p>GPTM Timer A PWM Interrupt Enable</p> <p>This bit enables interrupts in PWM mode on rising, falling, or both edges of the CCP output, as defined by the TAEVENT field in the GPTMCTL register.</p> <p>Value Description</p> <p>0 Interrupt is disabled.</p> <p>1 Interrupt is enabled.</p> <p>This bit is only valid in PWM mode.</p>
8	TAILD	R/W	0	<p>GPTM Timer A Interval Load Write</p> <p>Value Description</p> <p>0 Update the GPTMTAR register with the value in the GPTMTAILR register on the next cycle. If the prescaler is used, update the GPTMTAPS register with the value in the GPTMTAPR register on the next cycle.</p> <p>1 Update the GPTMTAR register with the value in the GPTMTAILR register on the next timeout. If the prescaler is used, update the GPTMTAPS register with the value in the GPTMTAPR register on the next timeout.</p> <p>Note the state of this bit has no effect when counting up.</p> <p>If the timer is disabled (TAEN is clear) when this bit is set, GPTMTAR and GPTMTAPS are updated when the timer is enabled. If the timer is stalled (TASTALL is set), GPTMTAR and GPTMTAPS are updated according to the configuration of this bit.</p>
7	TASNAPS	R/W	0	<p>GPTM Timer A Snap-Shot Mode</p> <p>Value Description</p> <p>0 Snap-shot mode is disabled.</p> <p>1 If Timer A is configured in the periodic mode, the actual free-running value of Timer A is loaded at the time-out event into the GPTM Timer A (GPTMTAR) register. If the timer prescaler is used, the prescaler snapshot is loaded into the GPTM Timer A (GPTMTAPR).</p>

Bit/Field	Name	Type	Reset	Description
6	TAWOT	R/W	0	<p>GPTM Timer A Wait-on-Trigger</p> <p>Value Description</p> <p>0 Timer A begins counting as soon as it is enabled.</p> <p>1 If Timer A is enabled (TAEN is set in the GPTMCTL register), Timer A does not begin counting until it receives a trigger from the timer in the previous position in the daisy chain, see Figure 11-9 on page 713. This function is valid for one-shot, periodic, and PWM modes.</p> <p>This bit must be clear for GP Timer Module 0, Timer A.</p>
5	TAMIE	R/W	0	<p>GPTM Timer A Match Interrupt Enable</p> <p>Value Description</p> <p>0 The match interrupt is disabled.</p> <p>1 An interrupt is generated when the match value in the GPTMTAMATCHR register is reached in the one-shot and periodic modes.</p>
4	TACDIR	R/W	0	<p>GPTM Timer A Count Direction</p> <p>Value Description</p> <p>0 The timer counts down.</p> <p>1 The timer counts up. When counting up, the timer starts from a value of 0x0.</p> <p>When in PWM or RTC mode, the status of this bit is ignored. PWM mode always counts down and RTC mode always counts up.</p>
3	TAAMS	R/W	0	<p>GPTM Timer A Alternate Mode Select</p> <p>The TAAMS values are defined as follows:</p> <p>Value Description</p> <p>0 Capture mode is enabled.</p> <p>1 PWM mode is enabled.</p> <p>Note: To enable PWM mode, you must also clear the TACMR bit and configure the TAMR field to 0x1 or 0x2.</p>
2	TACMR	R/W	0	<p>GPTM Timer A Capture Mode</p> <p>The TACMR values are defined as follows:</p> <p>Value Description</p> <p>0 Edge-Count mode</p> <p>1 Edge-Time mode</p>

Bit/Field	Name	Type	Reset	Description
1:0	TAMR	R/W	0x0	GPTM Timer A Mode The TAMR values are defined as follows: Value Description 0x0 Reserved 0x1 One-Shot Timer mode 0x2 Periodic Timer mode 0x3 Capture mode The Timer mode is based on the timer configuration defined by bits 2:0 in the GPTMCFG register.

Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TBAMS** bit, clear the **TBCMR** bit, and configure the **TBMR** field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTBMR** controls the modes for both Timer A and Timer B.

Important: Bits in this register should only be changed when the **TBEN** bit in the **GPTMCTL** register is cleared.

2	TBCMR	R/W	0	<p>GPTM Timer B Capture Mode</p> <p>The TBCMR values are defined as follows:</p> <p>Value Description</p> <p>0 Edge-Count mode</p> <p>1 Edge-Time mode</p>

Bit/Field	Name	Type	Reset	Description
1:0	TBMR	R/W	0x0	GPTM Timer B Mode The TBMR values are defined as follows: Value Description 0x0 Reserved 0x1 One-Shot Timer mode 0x2 Periodic Timer mode 0x3 Capture mode The timer mode is based on the timer configuration defined by bits 2:0 in the GPTMCFG register.

Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

Important: Bits in this register should only be changed when the **TnEN** bit for the respective timer is cleared.

GPTM Control (GPTMCTL)

Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

GPTM Interrupt Mask (GPTMIMR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000

Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

GPTM Raw Interrupt Status (GPTMRIS)

2	CAERIS	RO	0	<p>GPTM Timer A Capture Mode Event Raw Interrupt</p> <p>Value Description</p> <p>1 A capture mode event has occurred for Timer A. This interrupt asserts when the subtimer is configured in Input Edge-Time mode or when configured in PWM mode with the PWM interrupt enabled by setting the <code>TAPWMIIE</code> bit in the GPTMTAMR.</p> <p>0 The capture mode event for Timer A has not occurred.</p> <p>This bit is cleared by writing a 1 to the <code>CAECINT</code> bit in the GPTMICR register.</p>
1	CAMRIS	RO	0	<p>GPTM Timer A Capture Mode Match Raw Interrupt</p> <p>Value Description</p> <p>1 A capture mode match has occurred for Timer A. This interrupt asserts when the values in the GPTMTAR and GPTMTAPR match the values in the GPTMTAMATCHR and GPTMTAPMR when configured in Input Edge-Time mode.</p> <p>0 The capture mode match for Timer A has not occurred.</p> <p>This bit is cleared by writing a 1 to the <code>CAMCINT</code> bit in the GPTMICR register.</p>
0	TATORIS	RO	0	<p>GPTM Timer A Time-Out Raw Interrupt</p> <p>Value Description</p> <p>1 Timer A has timed out. This interrupt is asserted when a one-shot or periodic mode timer reaches its count limit (0 or the value loaded into GPTMTAILR, depending on the count direction).</p> <p>0 Timer A has not timed out.</p> <p>This bit is cleared by writing a 1 to the <code>TATOCINT</code> bit in the GPTMICR register.</p>

Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

GPTM Masked Interrupt Status (GPTMMIS)

0	TATOCINT	W1C	0	GPTM Timer A Time-Out Raw Interrupt Writing a 1 to this bit clears the TATORIS bit in the GPTMRIS register and the TATOMIS bit in the GPTMMIS register.

Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAILR** contains bits 31:0 of the 64-bit count and the **GPTM Timer B Interval Load (GPTMTBILR)** register contains bits 63:32.

GPTM Timer A Interval Load (GPTMTAILR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 32/64-bit Wide Timer 0 base: 0x4003.6000
 32/64-bit Wide Timer 1 base: 0x4003.7000
 32/64-bit Wide Timer 2 base: 0x4004.C000
 32/64-bit Wide Timer 3 base: 0x4004.D000
 32/64-bit Wide Timer 4 base: 0x4004.E000
 32/64-bit Wide Timer 5 base: 0x4004.F000
 Offset 0x028
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TAILR	R/W	0xFFFF.FFFF	GPTM Timer A Interval Load Register Writing this field loads the counter for Timer A. A read returns the current value of GPTMTAILR .

Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAILR** contains bits 31:0 of the 64-bit count and the **GPTMTBILR** register contains bits 63:32.

31:0	TBILR	R/W	0x0000.FFFF (for 16/32-bit) 0xFFFF.FFFF (for 32/64-bit)	GPTM Timer B Interval Load Register Writing this field loads the counter for Timer B. A read returns the current value of GPTMTBILR . When a 16/32-bit GPTM is in 32-bit mode, writes are ignored, and reads return the current value of GPTMTBILR .

Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAMATCHR** contains bits 31:0 of the 64-bit match value and the **GPTM Timer B Match (GPTMTBMATCHR)** register contains bits 63:32.

Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM and bits 47:32 in the 32-bit modes of the 32/64-bit Wide GPTM.

Register 18: GPTM Timer A (GPTMTAR), offset 0x048

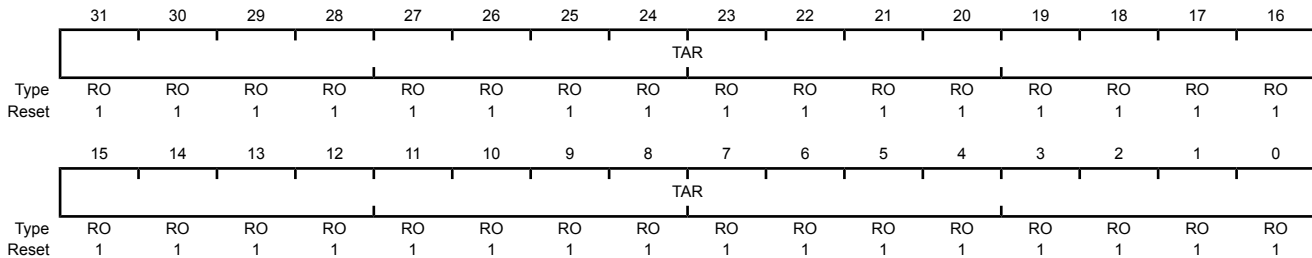

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAR** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B (GPTMTBR)** register contains bits 63:32. In a 32-bit mode, the value of the prescaler is stored in the **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register.

GPTM Timer A (GPTMTAR)

 32/64-bit Wide Timer 3 base: 0x4004.D000
 32/64-bit Wide Timer 4 base: 0x4004.E000
 32/64-bit Wide Timer 5 base: 0x4004.F000
 Offset 0x048
 Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TAR	RO	0xFFFF.FFFF	GPTM Timer A Register A read returns the current value of the GPTM Timer A Count Register , in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 19: GPTM Timer B (GPTMTBR), offset 0x04C

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAR** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B (GPTMTBR)** register contains bits 63:32. In a 32-bit mode, the value of the prescaler is stored in the **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register.

GPTM Timer B (GPTMTBR)

Bit/Field	Name	Type	Reset	Description
31:0	TBR	RO	0x0000.FFFF (for 16/32-bit) 0xFFFF.FFFF (for 32/64-bit)	GPTM Timer B Register A read returns the current value of the GPTM Timer B Count Register , in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler its 31:24 always read as 0.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAV** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B Value (GPTMTBV)** register contains bits 63:32. In a 32-bit mode, the current, free-running value of the prescaler is stored in the **GPTM Timer A Prescale Value (GPTMTAPV)** register.

GPTM Timer A Value (GPTMTAV)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000

 32/64-bit Wide Timer 4 base: 0x4004.E000
 32/64-bit Wide Timer 5 base: 0x4004.F000
 Offset 0x050
 Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TAV	RW	0xFFFF.FFFF	GPTM Timer A Value A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the GPTMTAR register on the next clock cycle.

Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler bits 31:24 always read as 0.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTBV** contains bits 63:32 of the 64-bit timer value and the **GPTM Timer A Value (GPTMTAV)** register contains bits 31:0. In a 32-bit mode, the current, free-running value of the prescaler is stored in the **GPTM Timer B Prescale Value (GPTMTBPV)** register.

				Value Description
				1 Timer A and Timer B counters are 32 bits each with a 16-bit prescale counter.
				0 Timer A and Timer B counters are 16 bits each with an 8-bit prescale counter.

12 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The LM4F120B2QR microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other is clocked by the PIOSC (Watchdog Timer 1). The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The Stellaris[®] LM4F120B2QR controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

12.1 Block Diagram

Figure 12-1. WDT Module Block Diagram

12.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the `INTTYPE` bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the `RESEN` bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

12.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

12.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **WDT** bit in the **RCGC0** register, see page 282.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. If the Watchdog is configured to trigger system resets, set the **RESEN** bit in the **WDTCTL** register.
4. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
5. Set the **INTEN** bit in the **WDTCTL** register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

12.4 Register Map

Table 12-1 on page 771 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 282).

Table 12-1. Watchdog Timers Register Map

Offset	Name	Type	Reset	Description	See page
0x000	WDTLOAD	R/W	0xFFFF.FFFF	Watchdog Load	772

12.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0x000
 Type R/W, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDTLOAD															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit/Field	Name	Type	Reset	Description
31:0	WDTLOAD	R/W	0xFFFF.FFFF	Watchdog Load Value

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDTVALUE															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDTVALUE															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit/Field	Name	Type	Reset	Description
31:0	WDTVALUE	RO	0xFFFF.FFFF	Watchdog Value Current value of the 32-bit down counter.

Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the `INTEN` bit, all subsequent writes to the `INTEN` bit are ignored. The only mechanism that can re-enable writes to this bit is a hardware reset.

Important: Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The `WRC` bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for `WRC=1` prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a `WRC` bit.

Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type R/W, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Once enabled, all writes are ignored.</td> </tr> </tbody> </table>	Value	Description	0	Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).	1	Interrupt event enabled. Once enabled, all writes are ignored.
Value	Description									
0	Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).									
1	Interrupt event enabled. Once enabled, all writes are ignored.									

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x00C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	WDTINTCLR	WO	-	Watchdog Interrupt Clear

Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

Watchdog Raw Interrupt Status (WDTRIS)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0x010
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTRIS	RO	0	Watchdog Raw Interrupt Status
				Value Description
				1 A watchdog time-out event has occurred.
				0 The watchdog has not timed out.

Register 6: Watchdog Masked Interrupt Status (WDTMIS), offset 0x014

This register is the masked interrupt status register. The value of this register is the logical AND of the raw interrupt bit and the Watchdog interrupt enable bit.

Watchdog Masked Interrupt Status (WDTMIS)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0x014
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTMIS	RO	0	Watchdog Masked Interrupt Status

Value	Description
1	A watchdog time-out event has been signalled to the interrupt controller.
0	The watchdog has not timed out or the watchdog timer interrupt is masked.

Register 7: Watchdog Test (WDTTEST), offset 0x418

This register provides user-enabled stalling when the microcontroller asserts the CPU halt flag during debug.

Watchdog Test (WDTTEST)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x418

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved							STALL	reserved

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	STALL	R/W	0	Watchdog Stall Enable
				Value Description
				1 If the microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.
				0 The watchdog timer continues counting if the microcontroller is stopped with a debugger.
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0xC00
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:0	WDTLOCK	R/W	0x0000.0000	Watchdog Lock A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates. A read of this register returns the following values: <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0000.0001</td> <td>Locked</td> </tr> <tr> <td>0x0000.0000</td> <td>Unlocked</td> </tr> </tbody> </table>	Value	Description	0x0000.0001	Locked	0x0000.0000	Unlocked
Value	Description									
0x0000.0001	Locked									
0x0000.0000	Unlocked									

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

Watchdog Peripheral Identification 4 (WDTPeriphID4)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xFD0

13 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 12 input channels.

The Stellaris® ADC module features 12-bit conversion resolution and supports 12 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. A digital comparator function is included which allows the conversion value to be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 798.

The Stellaris LM4F120B2QR microcontroller provides two ADC modules with each having the following features:

- 12 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - GPIO
- Hardware averaging of up to 64 samples
- Digital comparison unit providing eight digital comparators
- Converter uses a VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground

- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each sample sequencer
 - ADC module uses burst requests for DMA

13.1 Block Diagram

The Stellaris microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 12 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 13-1 on page 794 shows how the two modules are connected to analog inputs and the system bus.

Figure 13-1. Implementation of Two ADC Blocks

Figure 13-2 on page 795 provides details on the internal configuration of the ADC controls and data registers.

Figure 13-2. ADC Module Block Diagram

13.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The A_{INx} signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. The A_{INx} analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding $AMSEL$ bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 13-1. Signals for ADC (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
AIN0	6	PE3	I	Analog	Analog-to-digital converter input 0.
AIN1	7	PE2	I	Analog	Analog-to-digital converter input 1.
AIN2	8	PE1	I	Analog	Analog-to-digital converter input 2.
AIN3	9	PE0	I	Analog	Analog-to-digital converter input 3.
AIN4	64	PD3	I	Analog	Analog-to-digital converter input 4.
AIN5	63	PD2	I	Analog	Analog-to-digital converter input 5.
AIN6	62	PD1	I	Analog	Analog-to-digital converter input 6.
AIN7	61	PD0	I	Analog	Analog-to-digital converter input 7.

Table 13-1. Signals for ADC (64LQFP) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
AIN8	60	PE5	I	Analog	Analog-to-digital converter input 8.
AIN9	59	PE4	I	Analog	Analog-to-digital converter input 9.
AIN10	58	PB4	I	Analog	Analog-to-digital converter input 10.
AIN11	57	PB5	I	Analog	Analog-to-digital converter input 11.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

13.3 Functional Description

The Stellaris ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the μ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

13.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 13-2 on page 796 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

Table 13-2. Samples and FIFO Depth of Sequencers

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUX_n)** and **ADC Sample Sequence Control (ADCSSCTL_n)** registers, where "n" corresponds to the sequence number. The **ADCSSMUX_n** fields select the input pin, while the **ADCSSCTL_n** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASEN_n** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SS_n** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 833.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTL_n** register, the **IE_n** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END**

bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the `END` bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO_n)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT_n)** registers along with `FULL` and `EMPTY` status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

13.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation
- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

Most of the ADC control logic runs at the ADC clock rate of 16 MHz. The internal ADC divider is configured for 16-MHz operation automatically by hardware when the system `XTAL` is selected with the PLL.

13.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the `MASK` bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding `IN` bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

13.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration. The ADC module provides a request signal from each sample sequencer to the associated dedicated channel of the μ DMA controller. The ADC does not support single transfer requests. A burst transfer request is asserted when the interrupt bit for the sample sequence is set (`IE` bit in the **ADCSSCTL_n** register is set).

The arbitration size of the μ DMA transfer must be a power of 2, and the associated IE bits in the **ADSSCTLn** register must be set. For example, if the μ DMA channel of SS0 has an arbitration size of four, the $IE3$ bit (4th sample) and the $IE7$ bit (8th sample) must be set. Thus the μ DMA request occurs every time 4 samples have been acquired. No other special steps are needed to enable the ADC module for μ DMA operation.

Refer to the “Micro Direct Memory Access (μ DMA)” on page 581 for more details about programming the μ DMA controller.

13.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

13.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on GPIO $PB4$, a GP Timer, and continuous sampling. The processor triggers sampling by setting the SSx bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

13.3.2.5 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or with one of 15 different discrete phases relative to each other. The sample time can be delayed from the standard sampling time in 22.5° increments up to 337.5° using the **ADC Sample Phase Control (ADCSPC)** register. Figure 13-3 on page 798 shows an example of various phase relationships at a 1 Msps rate.

Figure 13-3. ADC Sample Phases

This feature can be used to double the sampling rate of an input. Both ADC module 0 and ADC module 1 can be programmed to sample the same input. ADC module 0 could sample at the standard position (the $PHASE$ field in the **ADCSPC** register is 0x0). ADC module 1 can be configured to sample

at 180 (PHASE = 0x8). The two modules can be synchronized using the GSYNC and SYNCWAIT bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software could then combine the results from the two modules to create a sample rate of two million samples/second at 16 MHz as shown in Figure 13-4 on page 799.

Figure 13-4. Doubling the ADC Sample Rate

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident sampling of different signals. The sample sequence steps run coincidentally in both converters.
 - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
 - ADC Module 1, **ADCSPC** = 0x0, sampling AIN1
- Skewed sampling of the same signal. The sample sequence steps are 1/2 of an ADC clock (500 μ s for a 1Ms/s ADC) out of phase with each other. This configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 13-5 on page 799.
 - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
 - ADC Module 1, **ADCSPC** = 0x8, sampling AIN0

Figure 13-5. Skewed Sampling

13.3.2.6 Module Clocking

The module is clocked by a 16-MHz clock which can be sourced by a divided version of the PLL output, the PIOSC or an external source connected to MOSC (with the PLL in bypass mode). When the PLL is operating, the ADC clock is derived from the PLL $\div 25$ by default, however, the PIOSC can be used for the module clock using the **ADC Clock Configuration (ADCCC)** register. When the PLL is bypassed, the module clock source clock attached to the MOSC must be 16 MHz unless the PIOSC is used for the clock source. The ADC module can continue to operate in Deep-Sleep mode if the PIOSC is the ADC module clock source.

13.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 835). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 13-6 on page 800 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

Figure 13-6. Sample Averaging Example

13.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive

approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation. The ADC requires a 16-MHz clock. This clock can be a divided version of the PLL output, the PIOSC or a 16-MHz clock source connected to MOSC. The MOSC provides the best results, followed by the PLL divided down, and then the PIOSC. Figure 13-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 1180.

Figure 13-7. ADC Input Equivalency Diagram

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 220). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1180.

13.3.4.1 Voltage Reference

The ADC uses VREFA+ and VREFA- as references to produce a conversion value from the selected analog input. VREFA+ is connected to VDDA and VREFA- is connected to GNDA, as shown in Figure 13-8.

Figure 13-8. ADC Voltage Reference

The range of this conversion value is from 0x000 to 0xFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFA-; the 0xFFF value corresponds to the voltage level on VREFA+. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (\text{VREFA+} - \text{VREFA-}) / 4095$$

While the analog input pads can handle voltages beyond this range, the ADC conversions saturate in under-voltage and over-voltage cases. Analog input voltages above VREFA+ saturate at 0xFFF while those below VREFA- saturate at 0x000. Figure 13-9 on page 803 shows the ADC conversion function of the analog inputs.

Figure 13-9. ADC Conversion Result

13.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the D_n bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 13-3 on page 803). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 13-3. Differential Sampling Pairs

Differential Pair	Analog Inputs
0	0 and 1
1	2 and 3
2	4 and 5
3	6 and 7
4	8 and 9
5	10 and 11

The voltage sampled in differential mode is the difference between the odd and even channels:

ΔV (differential voltage) = V_{IN_EVEN} (even channel) – V_{IN_ODD} (odd channel), therefore:

- If $\Delta V = 0$, then the conversion result = 0x800
- If $\Delta V > 0$, then the conversion result > 0x800 (range is 0x800–0xFFF)
- If $\Delta V < 0$, then the conversion result < 0x800 (range is 0–0x800)

The differential pairs assign polarities to the analog inputs: the even-numbered input is always positive, and the odd-numbered input is always negative. In order for a valid conversion result to appear, the negative input must be in the range of $\pm (V_{REFA+} - V_{REFA-})$ of the positive input. If an analog input is greater than V_{REFA+} or less than V_{REFA-} (the valid range for analog inputs), the input voltage is clipped, meaning it appears as either V_{REFA+} or V_{REFA-} , respectively, to the ADC. Because both inputs can swing from V_{REFA-} to V_{REFA+} , the maximum difference in the signal voltage is $2 \times (V_{REFA+} - V_{REFA-})$. As a result, the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (V_{REFA+} - V_{REFA-})) / 4095$$

Figure 13-10 shows how the differential voltage, ΔV , is represented in ADC codes.

Figure 13-10. Differential Voltage Representation

13.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. This reference voltage, $SENSO$, is given by the following equation:

$$SENSO = 2.7 - ((T + 55) / 75)$$

This relation is shown in Figure 13-11 on page 805.

Figure 13-11. Internal Temperature Sensor Characteristic

The temperature sensor reading can be sampled in a sample sequence by setting the TS_n bit in the **ADCSSCTLn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (in °C) based on the ADC reading:

$$\text{Temperature} = 147.5 - ((225 \times \text{ADC}) / 4095)$$

13.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators. Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. If the observed signal moves out of the acceptable range, a processor interrupt can be generated. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be applied to three separate regions (low band, mid band, high band) as defined by the user.

13.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the S_nDCOP bits in the **ADC Sample Sequence n Operation (ADCSSOPn)** register. These selected ADC conversions are used by their respective

digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

Interrupts

The digital comparator interrupt function is enabled by setting the `CIE` bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the `DCONSx` bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

13.3.7.2 Operational Modes

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the `CIM` field in the **ADCDCCTLn** register.

Always Mode

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

Once Mode

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

Hysteresis-Always Mode

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

Hysteresis-Once Mode

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

13.3.7.3 Function Ranges

The two comparison values, `COMP0` and `COMP1`, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These

regions are referred to as the low-band (less than or equal to COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

Low-Band Operation

To operate in the low-band region, either the CIC field field in the ADCDCCTLn register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 13-12 on page 807. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 13-12. Low-Band Operation (CIC=0x0)

Mid-Band Operation

To operate in the mid-band region, either the CIC field field in the ADCDCCTLn register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according to the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 13-13 on page 808. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 13-13. Mid-Band Operation (CIC=0x1)

High-Band Operation

To operate in the high-band region, either the `CIC` field in the `ADCDCCTLn` register must be programmed to 0x3. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 13-14 on page 809. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 13-14. High-Band Operation (CIC=0x3)

13.4 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and programmed to a supported crystal frequency in the **RCC** register (see page 272). Using unsupported frequencies can cause faulty operation in the ADC module.

13.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 387).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 374). To find out which GPIO ports to enable, refer to “Signal Description” on page 795.
3. Set the GPIO **AFSEL** bits for the ADC input pins (see page 666). To determine which GPIOs to configure, see Table 21-4 on page 1156.
4. Configure the **AIN_x** signals to be analog inputs by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register (see page 677).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 682) in the associated GPIO block.

- If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

13.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

- Ensure that the sample sequencer is disabled by clearing the corresponding **ASEN_n** bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
- Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
- For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX_n** register.
- For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL_n** register. When programming the last nibble, ensure that the **END** bit is set. Failure to set the **END** bit causes unpredictable behavior.
- If interrupts are to be used, set the corresponding **MASK** bit in the **ADCIM** register.
- Enable the sample sequencer logic by setting the corresponding **ASEN_n** bit in the **ADCACTSS** register.

13.5 Register Map

Table 13-4 on page 810 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 387). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

13.6 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

ADC Active Sample Sequencer (ADCACTSS)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x000
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved												ASEN3	ASEN2	ASEN1	ASEN0	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	R/W	0	ADC SS3 Enable Value Description 1 Sample Sequencer 3 is enabled. 0 Sample Sequencer 3 is disabled.
2	ASEN2	R/W	0	ADC SS2 Enable Value Description 1 Sample Sequencer 2 is enabled. 0 Sample Sequencer 2 is disabled.
1	ASEN1	R/W	0	ADC SS1 Enable Value Description 1 Sample Sequencer 1 is enabled. 0 Sample Sequencer 1 is disabled.
0	ASEN0	R/W	0	ADC SS0 Enable Value Description 1 Sample Sequencer 0 is enabled. 0 Sample Sequencer 0 is disabled.

Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x004
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															INRDC
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	INRDC	RO	0	Digital Comparator Raw Interrupt Status Value Description 1 At least one bit in the ADDCISC register is set, meaning that a digital comparator interrupt has occurred. 0 All bits in the ADDCISC register are clear.
15:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status Value Description 1 A sample has completed conversion and the respective ADCSSCTL3 IEn bit is set, enabling a raw interrupt. 0 An interrupt has not occurred. This bit is cleared by writing a 1 to the IN3 bit in the ADCISC register.
2	INR2	RO	0	SS2 Raw Interrupt Status Value Description 1 A sample has completed conversion and the respective ADCSSCTL2 IEn bit is set, enabling a raw interrupt. 0 An interrupt has not occurred. This bit is cleared by writing a 1 to the IN2 bit in the ADCISC register.

Bit/Field	Name	Type	Reset	Description
1	INR1	RO	0	<p>SS1 Raw Interrupt Status</p> <p>Value Description</p> <p>1 A sample has completed conversion and the respective ADCSSCTL1 I_{En} bit is set, enabling a raw interrupt.</p> <p>0 An interrupt has not occurred.</p> <p>This bit is cleared by writing a 1 to the $IN1$ bit in the ADCISC register.</p>
0	INR0	RO	0	<p>SS0 Raw Interrupt Status</p> <p>Value Description</p> <p>1 A sample has completed conversion and the respective ADCSSCTL0 I_{En} bit is set, enabling a raw interrupt.</p> <p>0 An interrupt has not occurred.</p> <p>This bit is cleared by writing a 1 to the $IN0$ bit in the ADCISC register.</p>

Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently. Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the ADCRIS register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines.

ADC Interrupt Mask (ADCIM)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x008
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:20	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	DCONSS3	R/W	0	Digital Comparator Interrupt on SS3 Value Description 1 The raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS3 interrupt line. 0 The status of the digital comparators does not affect the SS3 interrupt status.
18	DCONSS2	R/W	0	Digital Comparator Interrupt on SS2 Value Description 1 The raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS2 interrupt line. 0 The status of the digital comparators does not affect the SS2 interrupt status.
17	DCONSS1	R/W	0	Digital Comparator Interrupt on SS1 Value Description 1 The raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS1 interrupt line. 0 The status of the digital comparators does not affect the SS1 interrupt status.

Bit/Field	Name	Type	Reset	Description
16	DCONSS0	R/W	0	Digital Comparator Interrupt on SS0 Value Description 1 The raw interrupt signal from the digital comparators (<i>INRDC</i> bit in the ADCRIS register) is sent to the interrupt controller on the SS0 interrupt line. 0 The status of the digital comparators does not affect the SS0 interrupt status.
15:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MASK3	R/W	0	SS3 Interrupt Mask Value Description 1 The raw interrupt signal from Sample Sequencer 3 (ADCRIS register <i>INR3</i> bit) is sent to the interrupt controller. 0 The status of Sample Sequencer 3 does not affect the SS3 interrupt status.
2	MASK2	R/W	0	SS2 Interrupt Mask Value Description 1 The raw interrupt signal from Sample Sequencer 2 (ADCRIS register <i>INR2</i> bit) is sent to the interrupt controller. 0 The status of Sample Sequencer 2 does not affect the SS2 interrupt status.
1	MASK1	R/W	0	SS1 Interrupt Mask Value Description 1 The raw interrupt signal from Sample Sequencer 1 (ADCRIS register <i>INR1</i> bit) is sent to the interrupt controller. 0 The status of Sample Sequencer 1 does not affect the SS1 interrupt status.
0	MASK0	R/W	0	SS0 Interrupt Mask Value Description 1 The raw interrupt signal from Sample Sequencer 0 (ADCRIS register <i>INR0</i> bit) is sent to the interrupt controller. 0 The status of Sample Sequencer 0 does not affect the SS0 interrupt status.

Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective **INR** and **MASK** bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence **INR_n** bits are still cleared via the **ADCISC** register, even if the **IN_n** bit is not set.

ADC Interrupt Status and Clear (ADCISC)

Bit/Field	Name	Type	Reset	Description
1:0	SS0	R/W	0x0	SS0 Priority This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 0. A priority encoding of 0x0 is highest and 0x3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.

Register 9: ADC Sample Phase Control (ADCSPC), offset 0x024

This register allows the ADC module to sample at one of 16 different discrete phases from 0.0° through 337.5°. For example, the sample rate could be effectively doubled by sampling a signal using one ADC module configured with the standard sample time and the second ADC module configured with a 180.0° phase lag.

Note: Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AIN_x input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

ADC Sample Phase Control (ADCSPC)

ADC0 base: 0x4003.8000

Register 10: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate **SS** bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate **SS** bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

ADC Processor Sample Sequence Initiate (ADCPSSI)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x028

Type R/W, reset -

Register 11: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from 2^{AVG} consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

ADC Sample Averaging Control (ADCSAC)

ADC0 base: 0x4003.8000

Bit/Field	Name	Type	Reset	Description
31:28	MUX7	R/W	0x0	8th Sample Input Select The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 0x1 indicates the input is AIN1.
27:24	MUX6	R/W	0x0	7th Sample Input Select The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
23:20	MUX5	R/W	0x0	6th Sample Input Select The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
19:16	MUX4	R/W	0x0	5th Sample Input Select The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
15:12	MUX3	R/W	0x0	4th Sample Input Select The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
11:8	MUX2	R/W	0x0	3rd Sample Input Select The MUX2 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

Bit/Field	Name	Type	Reset	Description
7:4	MUX1	R/W	0x0	2nd Sample Input Select The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
3:0	MUX0	R/W	0x0	1st Sample Input Select The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

Register 14: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

ADC Sample Sequence Control 0 (ADCSSCTL0)

ADC0 base: 0x4003.8000

Bit/Field	Name	Type	Reset	Description
31	TS7	R/W	0	8th Sample Temp Sensor Select
				Value Description
				1 The temperature sensor is read during the eighth sample of the sample sequence.
				0 The input pin specified by the ADCSSMUXn register is read during the eighth sample of the sample sequence.
30	IE7	R/W	0	8th Sample Interrupt Enable
				Value Description
				1 The raw interrupt signal (<code>INR0</code> bit) is asserted at the end of the eighth sample's conversion. If the <code>MASK0</code> bit in the ADCIM register is set, the interrupt is promoted to the interrupt controller.
				0 The raw interrupt is not asserted to the interrupt controller.
				It is legal to have multiple samples within a sequence generate interrupts.
29	END7	R/W	0	8th Sample is End of Sequence
				Value Description
				1 The eighth sample is the last sample of the sequence.
				0 Another sample in the sequence is the final sample.
				It is possible to end the sequence on any sample position. Software must set an <code>ENDn</code> bit somewhere within the sequence. Samples defined after the sample containing a set <code>ENDn</code> bit are not requested for conversion even though the fields may be non-zero.

Bit/Field	Name	Type	Reset	Description
28	D7	R/W	0	8th Sample Diff Input Select Value Description 1 The analog input is differentially sampled. The corresponding ADCSSMUXn nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". 0 The analog inputs are not differentially sampled. Because the temperature sensor does not have a differential option, this bit must not be set when the TS7 bit is set.
27	TS6	R/W	0	7th Sample Temp Sensor Select Same definition as TS7 but used during the seventh sample.
26	IE6	R/W	0	7th Sample Interrupt Enable Same definition as IE7 but used during the seventh sample.
25	END6	R/W	0	7th Sample is End of Sequence Same definition as END7 but used during the seventh sample.
24	D6	R/W	0	7th Sample Diff Input Select Same definition as D7 but used during the seventh sample.
23	TS5	R/W	0	6th Sample Temp Sensor Select Same definition as TS7 but used during the sixth sample.

3	TS0	R/W	0	1st Sample Temp Sensor Select Same definition as TS7 but used during the first sample.
2	IE0	R/W	0	1st Sample Interrupt Enable Same definition as IE7 but used during the first sample.
1	END0	R/W	0	1st Sample is End of Sequence Same definition as END7 but used during the first sample.
0	D0	R/W	0	1st Sample Diff Input Select Same definition as D7 but used during the first sample.

Register 15: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048

Register 16: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068

Register 17: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088

Register 18: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8

Important: This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO n (ADCSSFIFO_n)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Register 19: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C

Register 20: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C

Register 21: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C

Register 22: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

Register 25: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060

Register 26: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 838 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1)

Register 27: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064**Register 28: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the **END** bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 840 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

0	D0	R/W	0	1st Sample Diff Input Select Same definition as D7 but used during the first sample.

Register 29: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070**Register 30: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

ADC Sample Sequence 1 Operation (ADCSSOP1)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x070
 Type R/W, reset 0x0000.0000

0	S0DCOP	R/W	0	Sample 0 Digital Comparator Operation Same definition as S3DCOP but used during the first sample.

Register 31: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074

Register 32: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding S_nDCOP bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1)

ADC0 base: 0x4003.8000

14 Universal Asynchronous Receivers/Transmitters (UARTs)

The Stellaris[®] LM4F120B2QR controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 μ s) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem flow control (on UART1)
- LIN protocol support
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive

- Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

14.1 Block Diagram

Figure 14-1. UART Module Block Diagram

14.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset, with the exception of the **U0Rx** and **U0Tx** pins which default to the UART function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these UART signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOCTL)** register (page 683) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 14-1. Signals for UART (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
U0Rx	17	PA0 (1)	I	TTL	UART module 0 receive.
U0Tx	18	PA1 (1)	O	TTL	UART module 0 transmit.
U1CTS	15 29	PC5 (8) PF1 (1)	I	TTL	UART module 1 Clear To Send modem flow control input signal.
U1RTS	16 28	PC4 (8) PF0 (1)	O	TTL	UART module 1 Request to Send modem flow control output line.
U1Rx	16 45	PC4 (2) PB0 (1)	I	TTL	UART module 1 receive.
U1Tx	15 46	PC5 (2) PB1 (1)	O	TTL	UART module 1 transmit.
U2Rx	53	PD6 (1)	I	TTL	UART module 2 receive.
U2Tx	10	PD7 (1)	O	TTL	UART module 2 transmit.
U3Rx	14	PC6 (1)	I	TTL	UART module 3 receive.
U3Tx	13	PC7 (1)	O	TTL	UART module 3 transmit.
U4Rx	16	PC4 (1)	I	TTL	UART module 4 receive.
U4Tx	15	PC5 (1)	O	TTL	UART module 4 transmit.
U5Rx	59	PE4 (1)	I	TTL	UART module 5 receive.
U5Tx	60	PE5 (1)	O	TTL	UART module 5 transmit.
U6Rx	43	PD4 (1)	I	TTL	UART module 6 receive.
U6Tx	44	PD5 (1)	O	TTL	UART module 6 transmit.
U7Rx	9	PE0 (1)	I	TTL	UART module 7 receive.
U7Tx	8	PE1 (1)	O	TTL	UART module 7 transmit.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

14.3 Functional Description

Each Stellaris UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 898). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the **UARTEN** bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

14.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 14-2 on page 875 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

Figure 14-2. UART Character Frame

14.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 894) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 895). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if *HSE* in **UARTCTL** is clear) or 8 (if *HSE* is set).

The 6-bit fractional number (that is to be loaded into the *DIVFRAC* bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as *Baud8* and *Baud16*, depending on the setting of the *HSE* bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations. Note that the state of the *HSE* bit has no effect on clock generation in ISO 7816 smart card mode (when the *SMART* bit in the **UARTCTL** register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 896), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

14.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The **BUSY** bit in the **UART Flag (UARTFR)** register (see page 891) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The **BUSY** bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the $UnRx$ signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of $Baud_{16}$ or fourth cycle of $Baud_8$ depending on the setting of the **HSE** bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 874).

The start bit is valid and recognized if the $UnRx$ signal is still low on the eighth cycle of $Baud_{16}$ (**HSE** clear) or the fourth cycle of $Baud_8$ (**HSE** set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of $Baud_{16}$ or 8th cycle of $Baud_8$ (that is, one bit period later) according to the programmed length of the data characters and value of the **HSE** bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the $UnRx$ signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

14.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the $UnTx$ and $UnRx$ pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated $IrLPBaud_{16}$ signal (1.63 μ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCR** register. See page 893 for more information on IrDA low-power pulse-duration configuration.

Figure 14-3 on page 877 shows the UART transmit and receive signals, with and without IrDA modulation.

Figure 14-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

14.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (**SMART**) of the **UARTCTL** register is set, the **UnTx** signal is used as a bit clock, and the **UnRx** signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (**WLEN** bits 6:5 configured to 0x3) with EVEN parity (**PEN** set and **EPS** set). In this mode, the UART automatically uses 2 stop bits, and the **STP2** bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, **UnRx** is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

14.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control signals for UART1 when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

14.3.6.1 Signaling

The status signals provided by UART1 differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control signals are defined as:

- $\overline{\text{UICTS}}$ is Clear To Send
- $\overline{\text{UIRTS}}$ is Request To Send

When used as a DCE, the the modem flow control signals are defined as:

- $\overline{\text{UICTS}}$ is Request To Send
- $\overline{\text{UIRTS}}$ is Clear To Send

14.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

Hardware Flow Control (RTS/CTS)

Hardware flow control between two devices is accomplished by connecting the $\overline{\text{UIRTS}}$ output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the $\overline{\text{UICTS}}$ input.

The $\overline{\text{UICTS}}$ input controls the transmitter. The transmitter may only transmit data when the $\overline{\text{UICTS}}$ input is asserted. The $\overline{\text{UIRTS}}$ output signal indicates the state of the receive FIFO. $\overline{\text{UICTS}}$ remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 14-2 on page 878.

Table 14-2. Flow Control Mode

CTSEN	RTSEN	Description
1	1	RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

Note that when **RTSEN** is 1, software cannot modify the $\overline{\text{UIRTS}}$ output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

Software Flow Control (Modem Status Interrupts)

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the $\overline{\text{UICTS}}$ signal using bit 3 of the **UARTIM** register. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

14.3.7 LIN Support

The UART module offers hardware support for the LIN protocol as either a master or a slave. The LIN mode is enabled by setting the **LIN** bit in the **UARTCTL** register. A LIN message is identified by the use of a Sync Break at the beginning of the message. The Sync Break is a transmission of a series of 0s. The Sync Break is followed by the Sync data field (0x55). Figure 14-4 on page 879 illustrates the structure of a LIN message.

Figure 14-4. LIN Message

The UART should be configured as followed to operate in LIN mode:

1. Configure the UART for 1 start bit, 8 data bits, no parity, and 1 stop bit. Enable the Transmit FIFO.
2. Set the `LIN` bit in the `UARTCTL` register.

When preparing to send a LIN message, the TXFIFO should contain the Sync data (0x55) at FIFO location 0 and the Identifier data at location 1, followed by the data to be transmitted, and with the checksum in the final FIFO entry.

14.3.7.1 LIN Master

The UART is enabled to be the LIN master by setting the `MASTER` bit in the `UARTLCTL` register. The length of the Sync Break is programmable using the `BLEN` field in the `UARTLCTL` register and can be 13-16 bits (baud clock cycles).

14.3.7.2 LIN Slave

The LIN UART slave is required to adjust its baud rate to that of the LIN master. In slave mode, the LIN UART recognizes the Sync Break, which must be at least 13 bits in duration. A timer is provided to capture timing data on the 1st and 5th falling edges of the Sync field so that the baud rate can be adjusted to match the master.

After detecting a Sync Break, the UART waits for the synchronization field. The first falling edge generates an interrupt using the `LME1RIS` bit in the `UARTRIS` register, and the timer value is captured and stored in the `UARTLSS` register (T1). On the fifth falling edge, a second interrupt is generated using the `LME5RIS` bit in the `UARTRIS` register, and the timer value is captured again (T2). The actual baud rate can be calculated using $(T2-T1)/8$, and the local baud rate should be adjusted as needed. Figure 14-5 on page 880 illustrates the synchronization field.

Figure 14-5. LIN Synchronization Field

14.3.8 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the `9BITEN` bit in the `UART9BITADDR` register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or address range along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the `UART9BITADDR` register. The matching can be extended to an address range using the address mask `UART9BITAMASK` that is ANDed with `UART9BITADDR` to form the range. By default, the `UART9BITAMASK` is `0xFF`.

If the byte received that follows 9th bit set then it will be compared with `UART9BITADDRRNG` (address range read-only status register). Upon not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case μ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

14.3.9 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the `UART Data (UARTDR)` register (see page 886). Read operations of the `UARTDR` register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the `FEN` bit in `UARTLCRH` (page 896).

FIFO status can be monitored via the `UART Flag (UARTFR)` register (see page 891) and the `UART Receive Status (UARTSR)` register. Hardware monitors empty, full and overrun conditions. The `UARTFR` register contains empty and full flags (`TXFE`, `TXFF`, `RXFE`, and `RXFF` bits), and the `UARTSR` register shows overrun status via the `OE` bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 902). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and $\frac{7}{8}$. For example, if the $\frac{1}{4}$ option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the $\frac{1}{2}$ mark.

14.3.10 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met, or if the EOT bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 910).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 904) by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 907).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 913).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

14.3.11 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the **UARTCTL** register (see page 898). In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit should be set before the UART is enabled.

14.3.12 DMA Operation

The UART provides an interface to the μ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer

request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the μ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the **RXDMAE** bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the **TXDMAE** bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the **DMAERR** bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

If DMA is enabled, then the μ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the UART interrupt vector. Therefore, if interrupts are used for UART operation and DMA is enabled, the UART interrupt handler must be designed to handle the μ DMA completion interrupt.

See “Micro Direct Memory Access (μ DMA)” on page 581 for more details about programming the μ DMA controller.

14.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 379).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 374). To find out which GPIO port to enable, refer to Table 21-5 on page 1160.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 666). To determine which GPIOs to configure, see Table 21-4 on page 1156.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 668 and page 676).
5. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the UART signals to the appropriate pins (see page 683 and Table 21-5 on page 1160).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 379). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 374) in the System Control module. To find out which GPIO port to enable, refer to Table 21-5 on page 1160.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity

- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 875, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the **DIVINT** field of the **UARTIBRD** register (see page 894) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 895) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Optionally, configure the μ DMA channel (see “Micro Direct Memory Access (μ DMA)” on page 581) and enable the DMA option(s) in the **UARTDMACTL** register.
6. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

14.5 Register Map

Table 14-3 on page 884 lists the UART registers. The offset listed is a hexadecimal increment to the register’s address, relative to that UART’s base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

Note that the UART module clock must be enabled before the registers can be programmed (see page 379). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

Note: The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 898) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

Table 14-3. UART Register Map

14.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

Register 1: UART Data (UARTDR), offset 0x000

Important: This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

UART Data (UARTDR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	OE	RO	0	UART Overrun Error
				Value Description
				1 New data was received when the FIFO was full, resulting in data loss.
				0 No data has been lost due to a FIFO overrun.

Bit/Field	Name	Type	Reset	Description
10	BE	RO	0	<p>UART Break Error</p> <p>Value Description</p> <p>1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</p> <p>0 No break condition has occurred</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state), and the next valid start bit is received.</p>
9	PE	RO	0	<p>UART Parity Error</p> <p>Value Description</p> <p>1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.</p> <p>0 No parity error has occurred</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>
8	FE	RO	0	<p>UART Framing Error</p> <p>Value Description</p> <p>1 The received character does not have a valid stop bit (a valid stop bit is 1).</p> <p>0 No framing error has occurred</p>
7:0	DATA	R/W	0x00	<p>Data Transmitted or Received</p> <p>Data that is to be transmitted via the UART is written to this field. When read, this field contains the data that was received by the UART.</p>

Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

Read-Only Status Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000

31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3	OE	RO	0	UART Overrun Error
---	----	----	---	--------------------

Value Description

Value	Description
1	New data was received when the FIFO was full, resulting in data loss.
0	No data has been lost due to a FIFO overrun.

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

Bit/Field	Name	Type	Reset	Description
2	BE	RO	0	<p>UART Break Error</p> <p>Value Description</p> <p>1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</p> <p>0 No break condition has occurred</p> <p>This bit is cleared to 0 by a write to UARTECR.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.</p>
1	PE	RO	0	<p>UART Parity Error</p> <p>Value Description</p> <p>1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.</p> <p>0 No parity error has occurred</p> <p>This bit is cleared to 0 by a write to UARTECR.</p>
0	FE	RO	0	<p>UART Framing Error</p> <p>Value Description</p> <p>1 The received character does not have a valid stop bit (a valid stop bit is 1).</p> <p>0 No framing error has occurred</p> <p>This bit is cleared to 0 by a write to UARTECR.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>

Write-Only Error Clear Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000

Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal $F_{IrLPBaud16}$ clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the $F_{IrLPBaud16}$ clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where $F_{IrLPBaud16}$ is nominally 1.8432 MHz.

The divisor must be programmed such that $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$, resulting in a low-power pulse duration of 1.41–2.11 μs (three times the period of $F_{IrLPBaud16}$). The minimum frequency of $F_{IrLPBaud16}$ ensures that pulses less than one period of $F_{IrLPBaud16}$ are rejected, but pulses greater than 1.4 μs are accepted as valid pulses.

Note: Zero is an illegal value. Programming a zero value results in no $F_{IrLPBaud16}$ pulses being generated.

Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 875 for configuration details.

Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

6:5	WLEN	R/W	0x0	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows: <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>5 bits (default)</td> </tr> <tr> <td>0x1</td> <td>6 bits</td> </tr> <tr> <td>0x2</td> <td>7 bits</td> </tr> <tr> <td>0x3</td> <td>8 bits</td> </tr> </tbody> </table>	Value	Description	0x0	5 bits (default)	0x1	6 bits	0x2	7 bits	0x3	8 bits
Value	Description													
0x0	5 bits (default)													
0x1	6 bits													
0x2	7 bits													
0x3	8 bits													

Bit/Field	Name	Type	Reset	Description
4	FEN	R/W	0	UART Enable FIFOs Value Description 1 The transmit and receive FIFO buffers are enabled (FIFO mode). 0 The FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers.
3	STP2	R/W	0	UART Two Stop Bits Select Value Description 1 Two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received. When in 7816 smartcard mode (the <code>SMART</code> bit is set in the <code>UARTCTL</code> register), the number of stop bits is forced to 2. 0 One stop bit is transmitted at the end of a frame.
2	EPS	R/W	0	UART Even Parity Select Value Description 1 Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits. 0 Odd parity is performed, which checks for an odd number of 1s. This bit has no effect when parity is disabled by the <code>PEN</code> bit.
1	PEN	R/W	0	UART Parity Enable Value Description 1 Parity checking and generation is enabled. 0 Parity is disabled and no parity bit is added to the data frame.
0	BRK	R/W	0	UART Send Break Value Description 1 A Low level is continually output on the <code>UnTx</code> signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods). 0 Normal use.

Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (**TXE**) and Receive Enable (**RXE**) bits, which are set.

To enable the UART module, the **UARTEN** bit must be set. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Note: The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (**FEN**) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

				Value Description
				1 The UART is enabled.
				0 The UART is disabled.
				If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.

Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

UART Interrupt FIFO Level Select (UARTIFLS)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000

In this case, the setting of TXIFLSEL is ignored.

Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x098
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TIMER	RO	0x0000	Timer Value This field contains the value of the free-running timer.

Register 18: UART 9-Bit Self Address (UART9BITADDR), offset 0x0A4

The **UART9BITADDR** register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (**UART9BITAMASK**) is set to 0xFF. This register is used in conjunction with **UART9BITAMASK** to form a match for address-byte received.

UART 9-Bit Self Address (UART9BITADDR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x0A4
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15	9BITEN	R/W	0	Enable 9-Bit Mode Value Description 1 9-bit mode is enabled. 0 9-bit mode is disabled.
14:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ADDR	R/W	0x00	Self Address for 9-Bit Mode This field contains the address that should be matched when UART9BITAMASK is 0xFF.

Register 19: UART 9-Bit Self Address Mask (UART9BITAMASK), offset 0x0A8

The **UART9BITAMASK** register is used to enable the address mask for 9-bit mode. The lower address bits are masked to create a range of address to be matched with the received address byte.

UART 9-Bit Self Address Mask (UART9BITAMASK)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x0A8
 Type R/W, reset 0x0000.00FF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:8	RANGE	RO	0x00	Self Address Range for 9-Bit Mode Writing to the RANGE field does not have any effect; reading it reflects the ANDed output of the ADDR field in the UART9BITADDR register and the MASK field.
7:0	MASK	R/W	0xFF	Self Address Mask for 9-Bit Mode This field contains the address mask that creates a range of addresses that should be matched.

Register 20: UART Peripheral Properties (UARTPP), offset 0xFC0

The **UARTPP** register provides information regarding the properties of the UART module.

UART Peripheral Properties (UARTPP)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0xFC0

1	NB	RO	0x1	9-Bit Support
				Value Description
				1 The UART module provides support for the transmission of 9-bit data for RS-485 support.
				0 The UART module does not provide support for the transmission of 9-bit data for RS-485 support.
0	SC	RO	0x1	Smart Card Support
				Value Description
				1 The UART module provides smart card support.
				0 The UART module does not provide smart card support.

Register 21: UART Clock Configuration (UARTCC), offset 0xFC8

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Communication Clock Sources” on page 215.

Note: If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

UART Clock Configuration (UARTCC)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000

15 Synchronous Serial Interface (SSI)

The Stellaris® microcontroller includes four Synchronous Serial Interface (SSI) modules. Each SSI is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

The Stellaris LM4F120B2QR controller includes four SSI modules with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
 - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

15.1 Block Diagram

Figure 15-1. SSI Module Block Diagram

15.2 Signal Description

The following table lists the external signals of the SSI module and describes the function of each. The SSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset., with the exception of the SSI0Clk, SSI0Fss, SSI0Rx, and SSI0Tx pins which default to the SSI function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the SSI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the SSI function. The number in parentheses is the encoding that must be programmed into the PMCh field in the **GPIO Port Control**

(**GPIOCTL**) register (page 683) to assign the SSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 645.

Table 15-1. Signals for SSI (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
SSI0Clk	19	PA2 (2)	I/O	TTL	SSI module 0 clock.
SSI0Fss	20	PA3 (2)	I/O	TTL	SSI module 0 frame.
SSI0Rx	21	PA4 (2)	I	TTL	SSI module 0 receive.
SSI0Tx	22	PA5 (2)	O	TTL	SSI module 0 transmit.
SSI1Clk	30 61	PF2 (2) PD0 (2)	I/O	TTL	SSI module 1 clock.
SSI1Fss	31 62	PF3 (2) PD1 (2)	I/O	TTL	SSI module 1 frame.
SSI1Rx	28 63	PF0 (2) PD2 (2)	I	TTL	SSI module 1 receive.
SSI1Tx	29 64	PF1 (2) PD3 (2)	O	TTL	SSI module 1 transmit.
SSI2Clk	58	PB4 (2)	I/O	TTL	SSI module 2 clock.
SSI2Fss	57	PB5 (2)	I/O	TTL	SSI module 2 frame.
SSI2Rx	1	PB6 (2)	I	TTL	SSI module 2 receive.
SSI2Tx	4	PB7 (2)	O	TTL	SSI module 2 transmit.
SSI3Clk	61	PD0 (1)	I/O	TTL	SSI module 3 clock.
SSI3Fss	62	PD1 (1)	I/O	TTL	SSI module 3 frame.
SSI3Rx	63	PD2 (1)	I	TTL	SSI module 3 receive.
SSI3Tx	64	PD3 (1)	O	TTL	SSI module 3 transmit.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

15.3 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the μ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the μ DMA module. μ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 964).

15.3.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value **CPSDVSR** from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 957). The clock is further divided by a value from 1 to 256, which is $1 + \text{SCR}$, where **SCR** is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 950).

The frequency of the output clock **SSIClk** is defined by:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

Note: The PIOSC is used as the source for the `SSIClk` when the `CS` field in the **SSI Clock Configuration (SSICC)** register is configured to 0x1. For master mode, the system clock or the PIOSC must be at least two times faster than the `SSIClk`, with the restriction that `SSIClk` cannot be faster than 25 MHz. For slave mode, the system clock or the PIOSC must be at least 6 times faster than the `SSIClk`.

See “Synchronous Serial Interface (SSI)” on page 1182 to view SSI timing parameters.

15.3.2 FIFO Operation

15.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 954), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the `SSITx` pin.

In slave mode, the SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the `SSI` bit in the **RGCG1** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The SSI can be configured to generate an interrupt or a μ DMA request when the FIFO is empty.

15.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the `SSIRx` pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

15.3.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the four individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 958). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic

dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 959 and page 961, respectively).

The receive FIFO has a time-out period that is 32 periods at the rate of `SSIClk` (whether or not `SSIClk` is currently active) and is started when the RX FIFO goes from EMPTY to not-EMPTY. If the RX FIFO is emptied before 32 clocks have passed, the time-out period is reset. As a result, the ISR should clear the Receive FIFO Time-out Interrupt just after reading out the RX FIFO by writing a 1 to the `RTIC` bit in the **SSI Interrupt Clear (SSIICR)** register. The interrupt should not be cleared so late that the ISR returns before the interrupt is actually cleared, or the ISR may be re-activated unnecessarily.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely. This interrupt can be used to indicate when it is safe to turn off the SSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

15.3.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (`SSIClk`) is held inactive while the SSI is idle, and `SSIClk` transitions at the programmed frequency only during active transmission or reception of data. The idle state of `SSIClk` is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (`SSIFSS`) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the `SSIFSS` pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of `SSIClk` and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

15.3.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 15-2 on page 940 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

Figure 15-2. TI Synchronous Serial Frame Format (Single Transfer)

In this mode, $SSIClk$ and $SSIFss$ are forced Low, and the transmit data line $SSITx$ is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, $SSIFss$ is pulsed High for one $SSIClk$ period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of $SSIClk$, the MSB of the 4 to 16-bit data frame is shifted out on the $SSITx$ pin. Likewise, the MSB of the received data is shifted onto the $SSIRx$ pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of $SSIClk$. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of $SSIClk$ after the LSB has been latched.

Figure 15-3 on page 940 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 15-3. TI Synchronous Serial Frame Format (Continuous Transfer)

15.3.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the $SSIFss$ signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the $SSIClk$ signal are programmable through the SPO and SPH bits in the **SSISCR0** control register.

SPO Clock Polarity Bit

When the SPO clock polarity control bit is clear, it produces a steady state Low value on the $SSIClk$ pin. If the SPO bit is set, a steady state High value is placed on the $SSIClk$ pin when data is not being transferred.

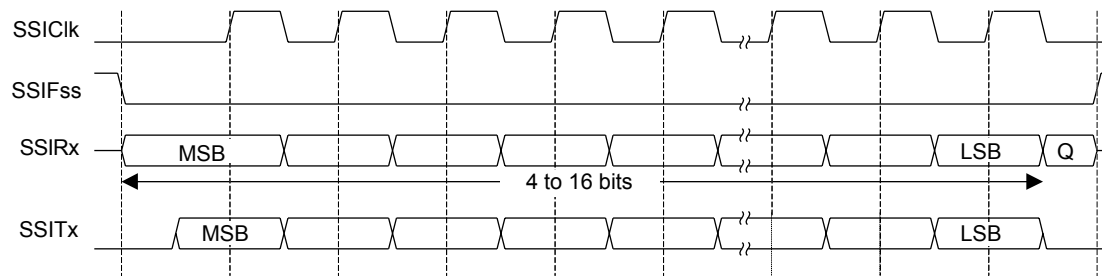

SPH Phase Control Bit

The *SPH* phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the *SPH* phase control bit is clear, data is captured on the first clock edge transition. If the *SPH* bit is set, data is captured on the second clock edge transition.

15.3.4.3 Freescale SPI Frame Format with *SPO=0* and *SPH=0*

Single and continuous transmission signal sequences for Freescale SPI format with *SPO=0* and *SPH=0* are shown in Figure 15-4 on page 941 and Figure 15-5 on page 941.

Figure 15-4. Freescale SPI Format (Single Transfer) with *SPO=0* and *SPH=0*

Note: Q is undefined.

Figure 15-5. Freescale SPI Format (Continuous Transfer) with *SPO=0* and *SPH=0*

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low, causing slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half $SSIClk$ period later, valid master data is transferred to the $SSITx$ pin. Once both the master and slave data have been set, the $SSIClk$ master clock pin goes High after one additional half $SSIClk$ period.

The data is now captured on the rising and propagated on the falling edges of the $SSIClk$ signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the $SSIFss$ line is returned to its idle High state one $SSIClk$ period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the $SSIFss$ signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the $SSIFss$ pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the $SSIFss$ pin is returned to its idle state one $SSIClk$ period after the last bit has been captured.

15.3.4.4 Freescale SPI Frame Format with $SPO=0$ and $SPH=1$

The transfer signal sequence for Freescale SPI format with $SPO=0$ and $SPH=1$ is shown in Figure 15-6 on page 942, which covers both single and continuous transfers.

Figure 15-6. Freescale SPI Frame Format with $SPO=0$ and $SPH=1$

Note: Q is undefined.

In this configuration, during idle periods:

- $SSIClk$ is forced Low
- $SSIFss$ is forced High
- The transmit data line $SSITx$ is arbitrarily forced Low
- When the SSI is configured as a master, it enables the $SSIClk$ pad
- When the SSI is configured as a slave, it disables the $SSIClk$ pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the $SSIFss$ master signal being driven Low. The master $SSITx$ output is enabled. After an additional one-half $SSIClk$ period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the $SSIClk$ is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the $SSIClk$ signal.

In the case of a single word transfer, after all bits have been transferred, the $SSIFss$ line is returned to its idle High state one $SSIClk$ period after the last bit has been captured.

For continuous back-to-back transfers, the $SSIF_{SS}$ pin is held Low between successive data words, and termination is the same as that of the single word transfer.

15.3.4.5 Freescale SPI Frame Format with $SPO=1$ and $SPH=0$

Single and continuous transmission signal sequences for Freescale SPI format with $SPO=1$ and $SPH=0$ are shown in Figure 15-7 on page 943 and Figure 15-8 on page 943.

Figure 15-7. Freescale SPI Frame Format (Single Transfer) with $SPO=1$ and $SPH=0$

Note: Q is undefined.

Figure 15-8. Freescale SPI Frame Format (Continuous Transfer) with $SPO=1$ and $SPH=0$

In this configuration, during idle periods:

- $SSIClk$ is forced High
- $SSIF_{SS}$ is forced High
- The transmit data line $SSITx$ is arbitrarily forced Low
- When the SSI is configured as a master, it enables the $SSIClk$ pad
- When the SSI is configured as a slave, it disables the $SSIClk$ pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the $SSIF_{SS}$ master signal being driven Low, causing slave data to be immediately transferred onto the $SSIRx$ line of the master. The master $SSITx$ output pad is enabled.

One-half period later, valid master data is transferred to the $SSITx$ line. Once both the master and slave data have been set, the $SSIClk$ master clock pin becomes Low after one additional half $SSIClk$ period, meaning that data is captured on the falling edges and propagated on the rising edges of the $SSIClk$ signal.

In the case of a single word transmission, after all bits of the data word are transferred, the $SSIF_{SS}$ line is returned to its idle High state one $SSIClk$ period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the $SSIF_{SS}$ signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the $SSIF_{SS}$ pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the $SSIF_{SS}$ pin is returned to its idle state one $SSIClk$ period after the last bit has been captured.

15.3.4.6 Freescale SPI Frame Format with $SPO=1$ and $SPH=1$

The transfer signal sequence for Freescale SPI format with $SPO=1$ and $SPH=1$ is shown in Figure 15-9 on page 944, which covers both single and continuous transfers.

Figure 15-9. Freescale SPI Frame Format with $SPO=1$ and $SPH=1$

Note: Q is undefined.

In this configuration, during idle periods:

- $SSIClk$ is forced High
- $SSIF_{SS}$ is forced High
- The transmit data line $SSITx$ is arbitrarily forced Low
- When the SSI is configured as a master, it enables the $SSIClk$ pad
- When the SSI is configured as a slave, it disables the $SSIClk$ pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the $SSIF_{SS}$ master signal being driven Low. The master $SSITx$ output pad is enabled. After an additional one-half $SSIClk$ period, both master and slave data are enabled onto their respective transmission lines. At the same time, $SSIClk$ is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the $SSIClk$ signal.

After all bits have been transferred, in the case of a single word transmission, the $SSIF_{SS}$ line is returned to its idle high state one $SSIClk$ period after the last bit has been captured.

For continuous back-to-back transmissions, the $SSIF_{SS}$ pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the $SSIF_{SS}$ pin is held Low between successive data words and termination is the same as that of the single word transfer.

15.3.4.7 MICROWIRE Frame Format

Figure 15-10 on page 945 shows the MICROWIRE frame format for a single frame. Figure 15-11 on page 946 shows the same format when back-to-back frames are transmitted.

Figure 15-10. MICROWIRE Frame Format (Single Frame)

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex and uses a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

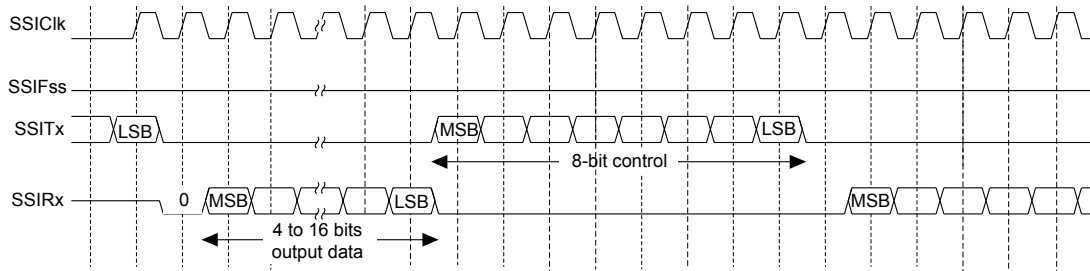

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic and the MSB of the 8-bit control frame to be shifted out onto the SSITx pin. SSIFss remains Low for the duration of the frame transmission. The SSIRx pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on each rising edge of SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, causing the data to be transferred to the receive FIFO.

Note: The off-chip slave device can tristate the receive line either on the falling edge of SSIClk after the LSB has been latched by the receive shifter or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFss line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

Figure 15-11. MICROWIRE Frame Format (Continuous Transfer)

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of $SSIClk$ after $SSIFss$ has gone Low. Masters that drive a free-running $SSIClk$ must ensure that the $SSIFss$ signal has sufficient setup and hold margins with respect to the rising edge of $SSIClk$.

Figure 15-12 on page 946 illustrates these setup and hold time requirements. With respect to the $SSIClk$ rising edge on which the first bit of receive data is to be sampled by the SSI slave, $SSIFss$ must have a setup of at least two times the period of $SSIClk$ on which the SSI operates. With respect to the $SSIClk$ rising edge previous to this edge, $SSIFss$ must have a hold of at least one $SSIClk$ period.

Figure 15-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements

15.3.5 DMA Operation

The SSI peripheral provides an interface to the μ DMA controller with separate channels for transmit and receive. The μ DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When μ DMA operation is enabled, the SSI asserts a μ DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst μ DMA transfer requests are handled automatically by the μ DMA controller depending how the μ DMA channel is configured. To enable μ DMA operation for the receive channel, the $RXDMAE$ bit of the **DMA Control (SSIDMACTL)** register should be set. To enable μ DMA operation for the transmit channel, the $TXDMAE$ bit of **SSIDMACTL** should be set. If μ DMA is enabled, then the μ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and μ DMA is enabled, the SSI interrupt handler must be designed to handle the μ DMA completion interrupt.

See “Micro Direct Memory Access (μ DMA)” on page 581 for more details about programming the μ DMA controller.

15.4 Initialization and Configuration

To enable and initialize the SSI, the following steps are necessary:

1. Enable the SSI module using the **RCGCSSI** register (see page 381).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 374). To find out which GPIO port to enable, refer to Table 21-5 on page 1160.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 666). To determine which GPIOs to configure, see Table 21-4 on page 1156.
4. Configure the **PMC_n** fields in the **GPIOPCTL** register to assign the SSI signals to the appropriate pins. See page 683 and Table 21-5 on page 1160.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the **SSE** bit in the **SSICR1** register is clear before making any configuration changes.
2. Select whether the SSI is a master or slave:
 - a. For master operations, set the **SSICR1** register to 0x0000.0000.
 - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
 - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the **SSICPSR** register.
4. Write the **SSICR0** register with the following configuration:
 - Serial clock rate (**SCR**)
 - Desired clock phase/polarity, if using Freescale SPI mode (**SPH** and **SPO**)
 - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (**FRF**)
 - The data size (**DSS**)
5. Optionally, configure the μ DMA channel (see “Micro Direct Memory Access (μ DMA)” on page 581) and enable the DMA option(s) in the **SSIDMACTL** register.
6. Enable the SSI by setting the **SSE** bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (**SPO**=1, **SPH**=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVR} * (1 + \text{SCR}))$$

$$1 \times 10^6 = 20 \times 10^6 / (\text{CPSDVR} * (1 + \text{SCR}))$$

In this case, if CPSDVR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the SSE bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the SSE bit in the **SSICR1** register.

15.5 Register Map

Table 15-2 on page 948 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: 0x4000.8000
- SSI1: 0x4000.9000
- SSI2: 0x4000.A000
- SSI3: 0x4000.B000

Note that the SSI module clock must be enabled before the registers can be programmed (see page 381). There must be a delay of 3 system clocks after the SSI module clock is enabled before any SSI module registers are accessed.

Note: The SSI must be disabled (see the SSE bit in the **SSICR1** register) before any of the control registers are reprogrammed.

Table 15-2. SSI Register Map

Offset	Name	Type	Reset	Description	See page
0x000	SSICR0	R/W	0x0000.0000	SSI Control 0	950
0x004	SSICR1	R/W	0x0000.0000	SSI Control 1	952
0x008	SSIDR	R/W	0x0000.0000	SSI Data	954
0x00C	SSISR	RO	0x0000.0003	SSI Status	955
0x010	SSICPSR	R/W	0x0000.0000	SSI Clock Prescale	957
0x014	SSIIM	R/W	0x0000.0000	SSI Interrupt Mask	958
0x018	SSIRIS	RO	0x0000.0008	SSI Raw Interrupt Status	959
0x01C	SSIMIS	RO	0x0000.0000	SSI Masked Interrupt Status	961
0x020	SSIICR	W1C	0x0000.0000	SSI Interrupt Clear	963
0x024	SSIDMACTL	R/W	0x0000.0000	SSI DMA Control	964

Table 15-2. SSI Register Map (continued)

Offset	Name	Type	Reset	Description	See page
0xFC8	SSICC	R/W	0x0000.0000	SSI Clock Configuration	965
0xFD0	SSIPeriphID4	RO	0x0000.0000	SSI Peripheral Identification 4	966

15.6 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

Register 1: SSI Control 0 (SSICR0), offset 0x000

The **SSICR0** register contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x000
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:8	SCR	R/W	0x00	SSI Serial Clock Rate This bit field is used to generate the transmit and receive bit rate of the SSI. The bit rate is: $BR = SysClk / (CPSDVSR * (1 + SCR))$ where CPSDVSR is an even value from 2-254 programmed in the SSICPSR register, and SCR is a value from 0-255.
7	SPH	R/W	0	SSI Serial Clock Phase This bit is only applicable to the Freescale SPI Format. The SPH control bit selects the clock edge that captures data and allows it to change state. This bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. Value Description 0 Data is captured on the first clock edge transition. 1 Data is captured on the second clock edge transition.
6	SPO	R/W	0	SSI Serial Clock Polarity Value Description 0 A steady state Low value is placed on the SSIClk pin. 1 A steady state High value is placed on the SSIClk pin when data is not being transferred.

Register 2: SSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x004
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved												EOT	SOD	MS	SSE	LBM
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	EOT	R/W	0	End of Transmission Value Description 0 The TXRIS interrupt indicates that the transmit FIFO is half full or less. 1 The End of Transmit interrupt mode for the TXRIS interrupt is enabled.
3	SOD	R/W	0	SSI Slave Mode Output Disable This bit is relevant only in the Slave mode ($MS=1$). In multiple-slave systems, it is possible for the SSI master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto the serial output line. In such systems, the TXD lines from multiple slaves could be tied together. To operate in such a system, the SOD bit can be configured so that the SSI slave does not drive the SSITx pin. Value Description 0 SSI can drive the SSITx output in Slave mode. 1 SSI must not drive the SSITx output in Slave mode.
2	MS	R/W	0	SSI Master/Slave Select This bit selects Master or Slave mode and can be modified only when the SSI is disabled ($SSE=0$). Value Description 0 The SSI is configured as a master. 1 The SSI is configured as a slave.

Bit/Field	Name	Type	Reset	Description
1	SSE	R/W	0	SSI Synchronous Serial Port Enable Value Description 0 SSI operation is disabled. 1 SSI operation is enabled. Note: This bit must be cleared before any control registers are reprogrammed.
0	LBM	R/W	0	SSI Loopback Mode Value Description 0 Normal serial port operation enabled. 1 Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.

Register 3: SSI Data (SSIDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the SSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the **SSITx** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the **SSE** bit in the **SSICR1** register is cleared, allowing the software to fill the transmit FIFO before enabling the SSI.

SSI Data (SSIDR)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x008
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	R/W	0x0000	SSI Receive/Transmit Data A read operation reads the receive FIFO. A write operation writes the transmit FIFO. Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

Register 4: SSI Status (SSISR), offset 0x00C

The **SSISR** register contains bits that indicate the FIFO fill status and the SSI busy status.

SSI Status (SSISR)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000

31:5	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	BSY	RO	0	SSI Busy Bit Value Description 0 The SSI is idle. 1 The SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.
3	RFF	RO	0	SSI Receive FIFO Full Value Description 0 The receive FIFO is not full. 1 The receive FIFO is full.
2	RNE	RO	0	SSI Receive FIFO Not Empty Value Description 0 The receive FIFO is empty. 1 The receive FIFO is not empty.
1	TNF	RO	1	SSI Transmit FIFO Not Full Value Description 0 The transmit FIFO is full. 1 The transmit FIFO is not full.

Bit/Field	Name	Type	Reset	Description
0	TFE	RO	1	SSI Transmit FIFO Empty
				Value Description
				0 The transmit FIFO is not empty.
				1 The transmit FIFO is empty.

Register 5: SSI Clock Prescale (SSICPSR), offset 0x010

The **SSICPSR** register specifies the division factor which is used to derive the **SSIClk** from the system clock. The clock is further divided by a value from 1 to 256, which is $1 + \text{SCR}$. **SCR** is programmed in the **SSICR0** register. The frequency of the **SSIClk** is defined by:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

SSI Clock Prescale (SSICPSR)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x010
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CPSDVSR	R/W	0x00	SSI Clock Prescale Divisor This value must be an even number from 2 to 254, depending on the frequency of SSIClk . The LSB always returns 0 on reads.

Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

SSI Interrupt Mask (SSIIM)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x014
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXIM	R/W	0	SSI Transmit FIFO Interrupt Mask Value Description 0 The transmit FIFO interrupt is masked. 1 The transmit FIFO interrupt is not masked.
2	RXIM	R/W	0	SSI Receive FIFO Interrupt Mask Value Description 0 The receive FIFO interrupt is masked. 1 The receive FIFO interrupt is not masked.
1	RTIM	R/W	0	SSI Receive Time-Out Interrupt Mask Value Description 0 The receive FIFO time-out interrupt is masked. 1 The receive FIFO time-out interrupt is not masked.
0	RORIM	R/W	0	SSI Receive Overrun Interrupt Mask Value Description 0 The receive FIFO overrun interrupt is masked. 1 The receive FIFO overrun interrupt is not masked.

Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

SSI Raw Interrupt Status (SSIRIS)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x018
 Type RO, reset 0x0000.0008

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved												TXRIS	RXRIS	RTRIS	RORRIS
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXRIS	RO	1	SSI Transmit FIFO Raw Interrupt Status Value Description 0 No interrupt. 1 If the EOT bit in the SSICR1 register is clear, the transmit FIFO is half full or less. If the EOT bit is set, the transmit FIFO is empty, and the last bit has been transmitted out of the serializer. This bit is cleared when the transmit FIFO is more than half full (if the EOT bit is clear) or when it has any data in it (if the EOT bit is set).
2	RXRIS	RO	0	SSI Receive FIFO Raw Interrupt Status Value Description 0 No interrupt. 1 The receive FIFO is half full or more. This bit is cleared when the receive FIFO is less than half full.
1	RTRIS	RO	0	SSI Receive Time-Out Raw Interrupt Status Value Description 0 No interrupt. 1 The receive time-out has occurred. This bit is cleared when a 1 is written to the RTIC bit in the SSI Interrupt Clear (SSIICR) register.

Bit/Field	Name	Type	Reset	Description
0	RORRIS	RO	0	SSI Receive Overrun Raw Interrupt Status Value Description 0 No interrupt. 1 The receive FIFO has overflowed This bit is cleared when a 1 is written to the RORIC bit in the SSI Interrupt Clear (SSIICR) register.

Register 8: SSI Masked Interrupt Status (SSIMIS), offset 0x01C

The **SSIMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

SSI Masked Interrupt Status (SSIMIS)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x01C
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXMIS	RO	0	SSI Transmit FIFO Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to the transmit FIFO being half full or less (if the <code>EOT</code> bit is clear) or due to the transmission of the last data bit (if the <code>EOT</code> bit is set). This bit is cleared when the transmit FIFO is more than half full (if the <code>EOT</code> bit is clear) or when it has any data in it (if the <code>EOT</code> bit is set).
2	RXMIS	RO	0	SSI Receive FIFO Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to the receive FIFO being half full or less. This bit is cleared when the receive FIFO is less than half full.
1	RTMIS	RO	0	SSI Receive Time-Out Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to the receive time out. This bit is cleared when a 1 is written to the <code>RTIC</code> bit in the SSI Interrupt Clear (SSIICR) register.

Bit/Field	Name	Type	Reset	Description
0	RORMIS	RO	0	SSI Receive Overrun Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to the receive FIFO overflowing. This bit is cleared when a 1 is written to the RORIC bit in the SSI Interrupt Clear (SSIICR) register.

Register 9: SSI Interrupt Clear (SSIICR), offset 0x020

The **SSIICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

SSI Interrupt Clear (SSIICR)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RTIC	W1C	0	SSI Receive Time-Out Interrupt Clear Writing a 1 to this bit clears the RTRIS bit in the SSIRIS register and the RTMIS bit in the SSIMIS register.
0	RORIC	W1C	0	SSI Receive Overrun Interrupt Clear Writing a 1 to this bit clears the RORRIS bit in the SSIRIS register and the RORMIS bit in the SSIMIS register.

Register 10: SSI DMA Control (SSIDMACTL), offset 0x024

The **SSIDMACTL** register is the μ DMA control register.

SSI DMA Control (SSIDMACTL)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0x024
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TXDMAE	R/W	0	Transmit DMA Enable Value Description 0 μ DMA for the transmit FIFO is disabled. 1 μ DMA for the transmit FIFO is enabled.
0	RXDMAE	R/W	0	Receive DMA Enable Value Description 0 μ DMA for the receive FIFO is disabled. 1 μ DMA for the receive FIFO is enabled.

Register 11: SSI Clock Configuration (SSICC), offset 0xFC8

The **SSICC** register controls the baud clock source for the SSI module.

Note: If the PIOSC is used for the SSI baud clock, the system clock frequency must be at least 16 MHz in Run mode.

SSI Clock Configuration (SSICC)

SSI0 base: 0x4000.8000
 SSI1 base: 0x4000.9000
 SSI2 base: 0x4000.A000
 SSI3 base: 0x4000.B000
 Offset 0xFC8
 Type R/W, reset 0x0000.0000

16 Inter-Integrated Circuit (I²C) Interface

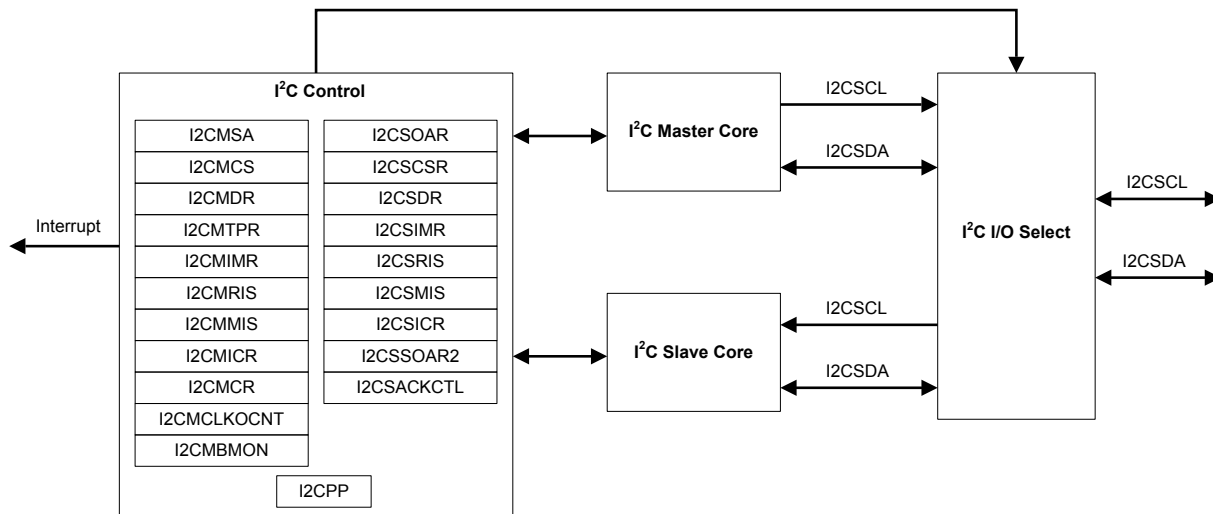

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM4F120B2QR microcontroller includes providing the ability to interact (both transmit and receive) with other I²C devices on the bus.

The Stellaris[®] LM4F120B2QR controller includes I²C modules with the following features:

- Devices on the I²C bus can be designated as either a master or a slave
 - Supports both transmitting and receiving data as either a master or a slave
 - Supports simultaneous master and slave operation
- Four I²C modes
 - Master transmit
 - Master receive
 - Slave transmit
 - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Clock low timeout interrupt
- Dual slave address capability
- Master and slave interrupt generation
 - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
 - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

16.1 Block Diagram

Figure 16-1. I²C Block Diagram

16.2 Signal Description

The following table lists the external signals of the I²C interface and describes the function of each. The I²C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset., with the exception of the I2C0SCL and I2CSDA pins which default to the I²C function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I²C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the I²C function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPTCL)** register (page 683) to assign the I²C signal to the specified GPIO port pin. Note that the I2CSCL pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 16-1. Signals for I2C (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
I2C0SCL	47	PB2 (3)	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C0SDA	48	PB3 (3)	I/O	OD	I ² C module 0 data.
I2C1SCL	23	PA6 (3)	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C1SDA	24	PA7 (3)	I/O	OD	I ² C module 1 data.
I2C2SCL	59	PE4 (3)	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C2SDA	60	PE5 (3)	I/O	OD	I ² C module 2 data.

Table 16-1. Signals for I²C (64LQFP) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
I2C3SCL	61	PD0 (3)	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C3SDA	62	PD1 (3)	I/O	OD	I ² C module 3 data.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

16.3 Functional Description

Each I²C module is comprised of both master and slave functions. For proper operation, the SDA pin must be configured as an open-drain signal. A typical I²C bus configuration is shown in Figure 16-2.

See “Inter-Integrated Circuit (I²C) Interface” on page 1184 for I²C timing diagrams.

Figure 16-2. I²C Bus Configuration

16.3.1 I²C Bus Functional Overview

The I²C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I²C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 980) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

16.3.1.1 START and STOP Conditions

The protocol of the I²C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 16-3.

Figure 16-3. START and STOP Conditions

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I²C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the **I²C Master Data (I2CMDR)** register. When the I²C module operates in Master receiver mode, the ACK bit is normally set causing the I²C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I²C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, two bits in the **I²C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus; while two bits in the **I²C Slave Masked Interrupt Status (I2CSMIS)** register allow start and stop conditions to be promoted to controller interrupts (when interrupts are enabled).

16.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 16-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

Figure 16-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 16-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

Figure 16-5. R/S Bit in First Byte

16.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 16-6).

Figure 16-6. Data Validity During Bit Transfer on the I²C Bus

16.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 982.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I²C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the I²C clock is pulled low after the last data bit until this register is written with the indicated response.

16.3.1.5 Clock Low Timeout

The I²C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I²C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I²C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The master can program this register with a count value that is acceptable to wait for the transaction to delay. The count is loaded at the START condition and counts down on every system clock edge. When the terminal count is reached, the I²C master can force a STOP condition on the bus the next time the slave releases the clock and abort the transaction.

The `CLKRIS` bit in the **I²C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the `CLKTO` bit in the **I²C Master Control/Status (I2CMCS)** register is set; this bit is cleared when a STOP condition is sent or during the I²C master reset.. The status of the raw SDA and SCL signals are readable by software through the `SDA` and `SCL` bits in the **I²C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

If the slave holds the clock low continuously, the only solution is to interrupt the processor using the `CLKRIS` bit and resolve the condition at higher protocol levels by resetting both the master and the remote slave.

16.3.1.6 Dual Address

The I²C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I²C slave provides an ACK on the bus if the address matches the `OAR` field in the **I2CSOAR** register. In dual address mode, the I²C slave provides an ACK on the bus if either the `OAR` field in the **I2CSOAR** register or the `OAR2` field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the `OAR2EN` bit in the **I2CSOAR2** register. The legacy address has always higher priority and to avoid confusion, and there is no disable on the legacy address.

The `OAR2SEL` bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

16.3.1.7 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a '1' (High) on SDA while another master transmits a '0' (Low) switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

16.3.2 Available Speed Modes

The I²C bus can run in either Standard mode (100 kbps) or Fast mode (400 kbps). The selected mode should match the speed of the other I²C devices on the bus.

16.3.2.1 Standard and Fast Modes

Standard and Fast modes are selected using a value in the **I²C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode or 400 kbps for Fast mode.

The I²C clock rate is determined by the parameters `CLK_PRD`, `TIMER_PRD`, `SCL_LP`, and `SCL_HP` where:

`CLK_PRD` is the system clock period

`SCL_LP` is the low phase of SCL (fixed at 6)

`SCL_HP` is the high phase of SCL (fixed at 4)

`TIMER_PRD` is the programmed value in the **I2CMTPR** register (see page 1002).

The I²C clock period is calculated as follows:

$$SCL_PERIOD = 2 \times (1 + TIMER_PRD) \times (SCL_LP + SCL_HP) \times CLK_PRD$$

For example:

$$CLK_PRD = 50 \text{ ns}$$

$$TIMER_PRD = 2$$

$$SCL_LP=6$$

$$SCL_HP=4$$

yields a SCL frequency of:

$$1/SCL_PERIOD = 333 \text{ Khz}$$

Table 16-2 gives examples of the timer periods that should be used to generate both Standard and Fast mode SCL frequencies based on various system clock frequencies.

Table 16-2. Examples of I²C Master Timer Period versus Speed Mode

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
4 MHz	0x01	100 Kbps	-	-
6 MHz	0x02	100 Kbps	-	-
12.5 MHz	0x06	89 Kbps	0x01	312 Kbps
16.7 MHz	0x08	93 Kbps	0x02	278 Kbps
20 MHz	0x09	100 Kbps	0x02	333 Kbps
25 MHz	0x0C	96.2 Kbps	0x03	312 Kbps
33 MHz	0x10	97.1 Kbps	0x04	330 Kbps
40 MHz	0x13	100 Kbps	0x04	400 Kbps
50 MHz	0x18	100 Kbps	0x06	357 Kbps
80 MHz	0x27	100 Kbps	0x09	400 Kbps

16.3.3 Interrupts

The I²C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master arbitration lost
- Master transaction error
- Master bus timeout
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

The I²C master and I²C slave modules have separate interrupt signals. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

16.3.3.1 I²C Master Interrupts

The I²C master module generates an interrupt when a transaction completes (either transmit or receive), when arbitration is lost, or when an error occurs during a transaction. To enable the I²C master interrupt, software must set the **IM** bit in the **I²C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the **ERROR** and **ARBLST** bits in the **I²C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction and to ensure that arbitration has not been lost. An error condition is asserted if the last transaction wasn't acknowledged by the slave. If an error is not detected and the master has not lost arbitration, the application can proceed with the transfer. The interrupt is cleared by writing a 1 to the **IC** bit in the **I²C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I²C Master Raw Interrupt Status (I2CMRIS)** register.

16.3.3.2 I²C Slave Interrupts

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by setting the **DATAIM** bit in the **I²C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I²C Slave Data (I2CSDR)** register, by checking the **RREQ** and **TREQ** bits of the **I²C Slave Control/Status (I2CCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the **FBR** bit is set along with the **RREQ** bit. The interrupt is cleared by setting the **DATAIC** bit in the **I²C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by setting the **STARTIM** and **STOPIM** bits of the **I²C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the **STOPIC** and **STARTIC** bits of the **I²C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I²C Slave Raw Interrupt Status (I2CSRIS)** register.

16.3.4 Loopback Operation

The I²C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the **LPBK** bit in the **I²C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

16.3.5 Command Sequence Flow Charts

This section details the steps required to perform the various I²C transfer types in both master and slave mode.

16.3.5.1 I²C Master Command Sequences

The figures that follow show the command sequences available for the I²C master.

Figure 16-7. Master Single TRANSMIT

Figure 16-8. Master Single RECEIVE

Figure 16-9. Master TRANSMIT with Repeated START

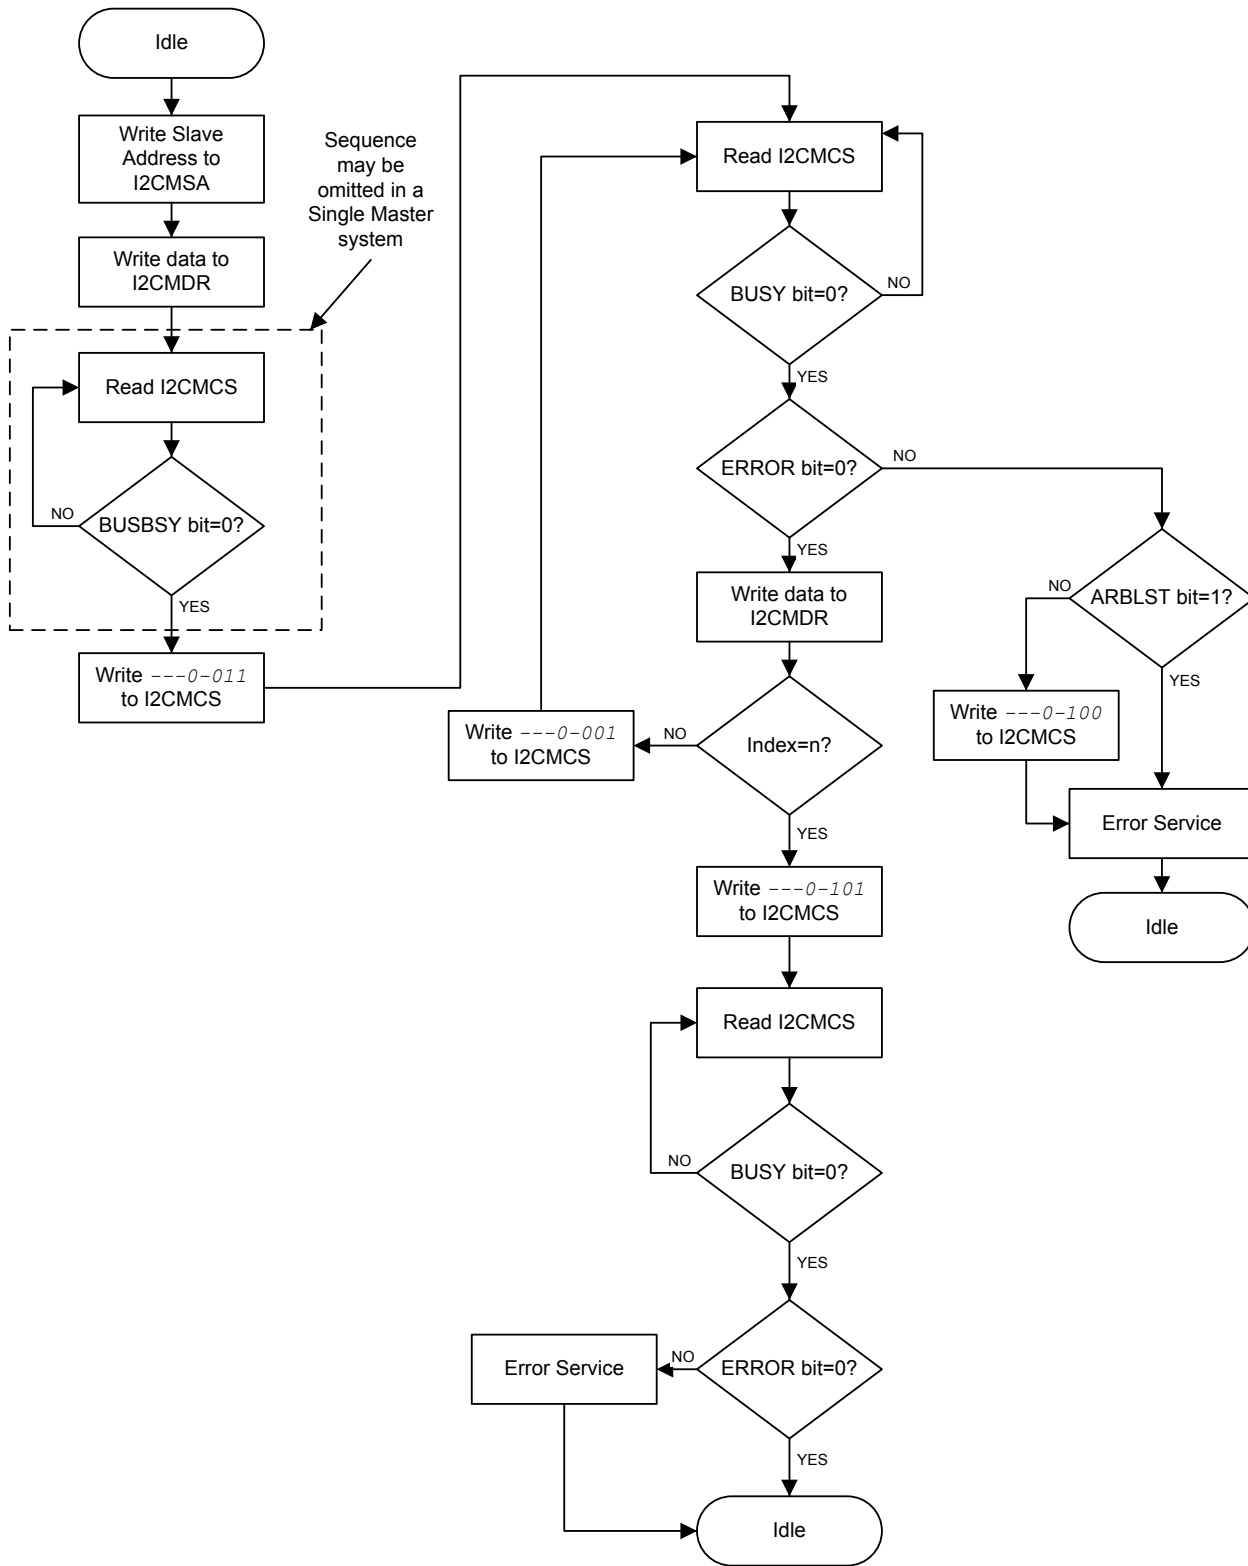

Figure 16-10. Master RECEIVE with Repeated START

Figure 16-11. Master RECEIVE with Repeated START after TRANSMIT with Repeated START

Figure 16-12. Master TRANSMIT with Repeated START after RECEIVE with Repeated START

16.3.5.2 I²C Slave Command Sequences

Figure 16-13 on page 992 presents the command sequence available for the I²C slave.

Figure 16-13. Slave Command Sequence

16.4 Initialization and Configuration

The following example shows how to configure the I²C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I²C clock using the **RCGCI2C** register in the System Control module (see page 383).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 374). To find out which GPIO port to enable, refer to Table 21-5 on page 1160.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 666). To determine which GPIOs to configure, see Table 21-4 on page 1156.
4. Enable the I²C pins for Open Drain operation. See page 671.
5. Configure the **PMC_n** fields in the **GPIOPCTL** register to assign the I²C signals to the appropriate pins. See page 683 and Table 21-5 on page 1160.
6. Initialize the I²C Master by writing the **I2CMCR** register with a value of 0x0000.0010.

7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL_LP} + \text{SCL_HP}) * \text{SCL_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the **I2CMTPR** register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.
12. Check the **ERROR** bit in the **I2CMCS** register to confirm the transmit was acknowledged.

16.5 Register Map

Table 16-3 on page 993 lists the I²C registers. All addresses given are relative to the I²C base address:

- I²C 0: 0x4002.0000
- I²C 1: 0x4002.1000
- I²C 2: 0x4002.2000
- I²C 3: 0x4002.3000

Note that the I²C module clock must be enabled before the registers can be programmed (see page 383). There must be a delay of 3 system clocks after the I²C module clock is enabled before any I²C module registers are accessed.

The `hw_i2c.h` file in the StellarisWare® Driver Library uses a base address of 0x800 for the I²C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that StellarisWare uses an offset between 0x000 and 0x018 with the slave base address.

16.6 Register Descriptions (I²C Master)

The remainder of this section lists and describes the I²C master registers, in numerical order by address offset.

Register 1: I²C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 Offset 0x000
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								SA							R/S
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:1	SA	R/W	0x00	I ² C Slave Address This field specifies bits A6 through A0 of the slave address.
0	R/S	R/W	0	Receive/Send The R/S bit specifies if the next operation is a Receive (High) or Transmit (Low).
				Value Description
				0 Transmit
				1 Receive

Register 2: I²C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I²C bus controller. When written, the control register configures the I²C controller operation.

The **START** bit generates the **START** or **REPEATED START** condition. The **STOP** bit determines if the cycle stops at the end of the data cycle or continues on to a repeated **START** condition. To generate a single transmit cycle, the **I²C Master Slave Address (I2CMSA)** register is written with the desired address, the **R/S** bit is cleared, and this register is written with **ACK=X** (0 or 1), **STOP=1**, **START=1**, and **RUN=1** to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I²C module operates in Master receiver mode, the **ACK** bit is normally set, causing the I²C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I²C bus controller requires no further data to be transmitted from the slave transmitter.

Read-Only Status Register

Write-Only Control Register

I²C Master Control/Status (I2CMCS)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 Offset 0x004
 Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ACK	WO	0	Data Acknowledge Enable Value Description 0 The received data byte is not acknowledged automatically by the master. 1 The received data byte is acknowledged automatically by the master. See field decoding in Table 16-4 on page 999.
2	STOP	WO	0	Generate STOP Value Description 0 The controller does not generate the STOP condition. 1 The controller generates the STOP condition. See field decoding in Table 16-4 on page 999.
1	START	WO	0	Generate START Value Description 0 The controller does not generate the START condition. 1 The controller generates the START or repeated START condition. See field decoding in Table 16-4 on page 999.
0	RUN	WO	0	I ² C Master Enable Value Description 0 The master is disabled. 1 The master is enabled to transmit or receive data. See field decoding in Table 16-4 on page 999.

Table 16-4. Write Field Decoding for I2CMCS[3:0] Field

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Idle	0	X ^a	0	1	1	START condition followed by TRANSMIT (master goes to the Master Transmit state).
	0	X	1	1	1	START condition followed by a TRANSMIT and STOP condition (master remains in Idle state).
	1	0	0	1	1	START condition followed by RECEIVE operation with negative ACK (master goes to the Master Receive state).
	1	0	1	1	1	START condition followed by RECEIVE and STOP condition (master remains in Idle state).
	1	1	0	1	1	START condition followed by RECEIVE (master goes to the Master Receive state).
	1	1	1	1	1	Illegal
	All other combinations not listed are non-operations.					NOP
Master Transmit	X	X	0	0	1	TRANSMIT operation (master remains in Master Transmit state).
	X	X	1	0	0	STOP condition (master goes to Idle state).
	X	X	1	0	1	TRANSMIT followed by STOP condition (master goes to Idle state).
	0	X	0	1	1	Repeated START condition followed by a TRANSMIT (master remains in Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state).
	1	0	0	1	1	Repeated START condition followed by a RECEIVE operation with a negative ACK (master goes to Master Receive state).
	1	0	1	1	1	Repeated START condition followed by a TRANSMIT and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master goes to Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					NOP.

Table 16-4. Write Field Decoding for I2CMCS[3:0] Field (continued)

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Master Receive	X	0	0	0	1	RECEIVE operation with negative ACK (master remains in Master Receive state).
	X	X	1	0	0	STOP condition (master goes to Idle state). ^b
	X	0	1	0	1	RECEIVE followed by STOP condition (master goes to Idle state).
	X	1	0	0	1	RECEIVE operation (master remains in Master Receive state).
	X	1	1	0	1	Illegal.
	1	0	0	1	1	Repeated START condition followed by RECEIVE operation with a negative ACK (master remains in Master Receive state).
	1	0	1	1	1	Repeated START condition followed by RECEIVE and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master remains in Master Receive state).
	0	X	0	1	1	Repeated START condition followed by TRANSMIT (master goes to Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state).
	All other combinations not listed are non-operations.					

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

Register 3: I²C Master Data (I2CMDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state.

I2C Master Data (I2CMDR)

I2C 0 base: 0x4002.0000

0	SCL	RO	0	I ² C SCL Status Value Description 1 The I2CSCL signal is high. 0 The I2CSCL signal is low.

16.7 Register Descriptions (I²C Slave)

The remainder of this section lists and describes the I²C slave registers, in numerical order by address offset.

Register 12: I²C Slave Own Address (I2CSOAR), offset 0x800

This register consists of seven address bits that identify the Stellaris I²C device on the I²C bus.

I2C Slave Own Address (I2CSOAR)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000

17 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The Stellaris® LM4F120B2QR microcontroller includes one CAN unit with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN_nTX and CAN_nRX signals

17.1 Block Diagram

Figure 17-1. CAN Controller Block Diagram

17.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 683) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 17-1. Signals for Controller Area Network (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
CAN0Rx	28 58 59	PF0 (3) PB4 (8) PE4 (8)	I	TTL	CAN module 0 receive.
CAN0Tx	31 57 60	PF3 (3) PB5 (8) PE5 (8)	O	TTL	CAN module 0 transmit.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

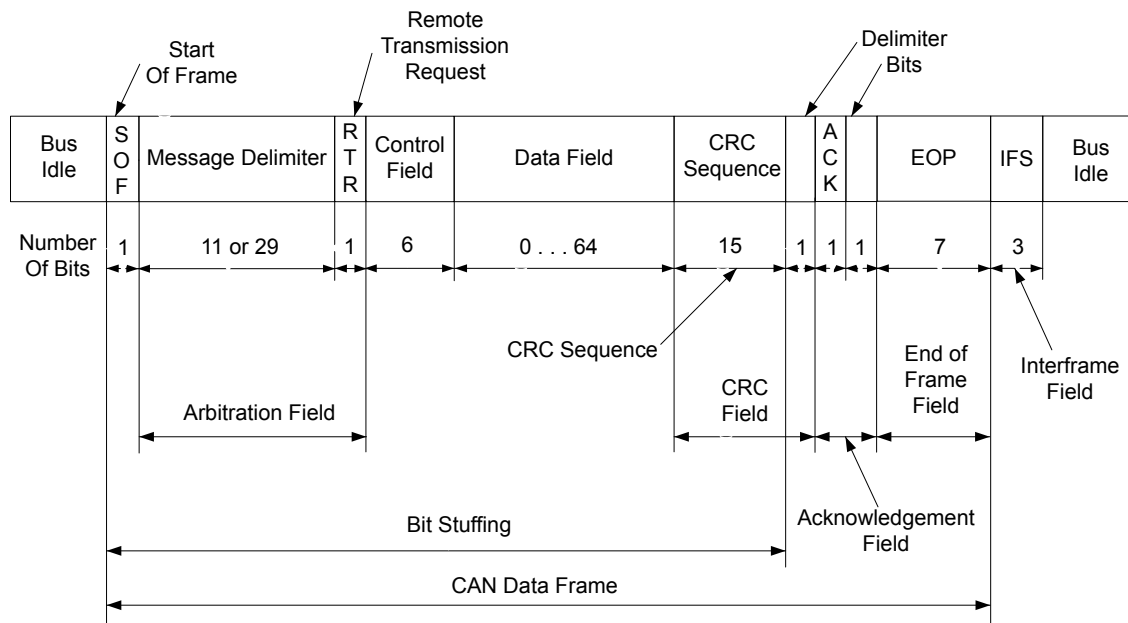

17.3 Functional Description

The Stellaris CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 17-2.

Figure 17-2. CAN Data/Remote Frame

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate

message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the Stellaris memory map, so the Stellaris CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. The message object memory cannot be directly accessed, so these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

17.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 282). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 289). To find out which GPIO port to enable, refer to Table 21-4 on page 1156. Set the GPIO **AFSEL** bits for the appropriate pins (see page 666). Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CAN signals to the appropriate pins. See page 683 and Table 21-5 on page 1160.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the **MSGVAL** bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the **INIT** and **CCE** bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the **INIT** bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the **MSGVAL** bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the **MSGVAL** bit again to indicate that the message object is once again valid.

17.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the `MNUM` bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate `TXRQST` bit in the **CAN Transmission Request n (CANTXRQn)** register and the `NEWDAT` bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (`MNUM`) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the `RMTEEN` bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the `TXRQST` bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The `MXTD` bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

17.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's `NEWDAT` bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the `TXRQST` bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the `TXIE` bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the `INTPND` bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

17.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
 - Set the `WRNRD` bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the `IDMASK`, `DIR`, and `MXTD` of the message object into the **CAN IFn** registers using the `MASK` bit
 - Specify whether to transfer the `ID`, `DIR`, `XTD`, and `MSGVAL` of the message object into the interface registers using the `ARB` bit
 - Specify whether to transfer the control bits into the interface registers using the `CONTROL` bit
 - Specify whether to clear the `INTPND` bit in the **CANIFnMCTL** register using the `CLRINTPND` bit
 - Specify whether to clear the `NEWDAT` bit in the **CANNWDAn** register using the `NEWDAT` bit
 - Specify which bits to transfer using the `DATAA` and `DATAB` bits
2. In the **CANIFnMSK1** register, use the `MSK[15:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[15:0]` in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the `MSK[12:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[12:0]` are used for bits [28:16] of the 29-bit message identifier; whereas `MSK[12:2]` are used for bits [10:0] of the 11-bit message identifier. Use the `MXTD` and `MDIR` bits to specify whether to use `XTD` and `DIR` for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure `ID[15:0]` in the **CANIFnARB1** register to are used for bits [15:0] of the message identifier and `ID[12:0]` in the **CANIFnARB2** register to are used for bits [28:16] of the message identifier. Set the `XTD` bit to indicate an extended identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure `ID[12:2]` in the **CANIFnARB2** register to are used for bits [10:0] of the message identifier. Clear the `XTD` bit to indicate a standard identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:
 - Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission

- Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set on the reception of a matching remote frame allowing automatic transmission
 - Set the `EOB` bit for a single message object
 - Configure the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
 8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
 9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

17.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WRNRD`, `DATAA` and `DATAB` bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the `TXRQST` bit in the **CANIFnMSKn** register.

To prevent the clearing of the `TXRQST` bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the `NEWDAT` and `TXRQST` bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, `NEWDAT` is cleared as soon as the new transmission has started.

17.3.6 Accepting Received Message Objects

When the arbitration and control field (the `ID` and `XTD` bits in the **CANIFnARB2** and the `RMTEN` and `DLC[3:0]` bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the `UMASK` bit in the **CANIFnMCTL** register. Each valid message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

17.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The **NEWDAT** bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the **NEWDAT** bit is already set, the **MSGLST** bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the **RXIE** bit of the **CANIFnMCTL** register should be set. In this case, the **INTPND** bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The **TXRQST** bit of this message object should be cleared to prevent the transmission of a remote frame.

17.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

Table 17-2. Message Object Configurations

Configuration in CANIFnMCTL	Description
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 1 (set the TXRQST bit of the CANIFnMCTL register at reception of the frame to enable transmission) ■ UMASK = 1 or 0 	At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 0 (ignore mask in the CANIFnMSKn register) 	At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the CANIFnMSKn register) for acceptance filtering) 	At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the Stellaris controller does not have readily available data. The software must fill the data and answer the frame manually.

17.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message

object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

17.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1026 section, except that the **WRNRD** bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1026 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the **UMASK** bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the **MSK[12:0]** bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that **MSK[12:0]** are used for bits [28:16] of the 29-bit message identifier; whereas **MSK[12:2]** are used for bits [10:0] of the 11-bit message identifier. Use the **MXTD** and **MDIR** bits to specify whether to use **XTD** and **DIR** for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the **UMASK** bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1026 section to program **XTD** and **ID** bits for the message identifier to be received; set the **MSGVAL** bit to indicate a valid message; and clear the **DIR** bit to specify receive.
5. In the **CANIFnMCTL** register:
 - Optionally set the **UMASK** bit to enable the mask (**MSK**, **MXTD**, and **MDIR** specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the **RXIE** bit to enable the **INTPND** bit to be set after a successful reception
 - Clear the **RMTEN** bit to leave the **TXRQST** bit unchanged
 - Set the **EOB** bit for a single message object
 - Configure the **DLC[3:0]** field to specify the size of the data frame

Take care during this configuration not to set the **NEWDAT**, **MSGLST**, **INTPND** or **TXRQST** bits.
6. Program the number of the message object to be received in the **MNUM** field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in **DATA[7:0]** in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSK_n**, configure which groups of frames are received by a message object. The **UMASK** bit in the **CANIFnMCTL** register enables the **MSK** bits in the **CANIFnMSK_n** register to filter which frames are received. The **MXTD** bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

17.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSK_n**, **CANIFnARB_n**, and **CANIFnMCTL**). Additionally, the **NEWDAT** and **INTPND** bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARB_n** registers show the full, unmasked ID for the received message.

The **NEWDAT** bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The **MSGLST** bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. **MSGLST** is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the **TXRQST** bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the **TXRQST** bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

17.3.11.1 Configuration of a FIFO Buffer

With the exception of the **EOB** bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 1029). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The **EOB** bit of all message objects of a FIFO buffer except the last one must be cleared. The **EOB** bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

17.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the **NEWDAT** of the **CANIFnMCTL** register bit of this message object is set. By setting **NEWDAT** while **EOB** is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the **NEWDAT** bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the **NEWDAT** bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

17.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the **TXRQST** and **CLRINTPND** bits in the **CANIFnCMSK** register should be set such that the **NEWDAT** and **INTPEND** bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message could be placed in the location of any message object for which the **NEWDAT** bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 17-3 on page 1032 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 17-3. Message Objects in a FIFO Buffer

17.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's `INTPND` bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier `INTID` in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the `INTID` field is different from 0, then an interrupt is pending. If the `IE` bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the `INTID` field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until `IE` is cleared, which disables interrupts from the CAN controller.

The `INTID` field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The `SIE` bit in the **CANCTL** register controls whether a change of the `RXOK`, `TXOK`, and `LEC` bits in the **CANSTS** register can cause an interrupt. The `EIE` bit in the **CANCTL** register controls whether a change of the `BOFF` and `EWARN` bits in the **CANSTS** register can cause an interrupt. The `IE` bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the `IE` bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the `RXOK`, `TXOK`, and `LEC` bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the `INTID` bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's `INTPND` bit at the same time by setting the `CLRINTPND` bit in the **CANIFnCMSK** register. Once the `INTPND` bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

17.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the `TEST` bit in the **CANCTL** register. Once in Test Mode, the `TX[1:0]`, `LBACK`, `SILENT` and `BASIC` bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The `RX` bit in the **CANTST** register allows monitoring of the `CANnRX` signal. All **CANTST** register functions are disabled when the `TEST` bit is cleared.

17.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the `SILENT` bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

17.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the `CANnTX` signal on to the `CANnRX` signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the `LBACK` bit in the `CANTST` register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the `CANnRX` signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the `CANnTX` signal.

17.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the `CANnTX` and `CANnRX` signals. In this mode, the `CANnRX` signal is disconnected from the CAN Controller and the `CANnTX` signal is held recessive. This mode is enabled by setting both the `LBACK` and `SILENT` bits in the `CANTST` register.

17.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the `BUSY` bit of the `CANIF1CRQ` register. The CANIF1 registers are locked while the `BUSY` bit is set. The `BUSY` bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the `BUSY` bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the `BUSY` bit in the `CANIF1CRQ` register while the CANIF1 registers are locked. If the CPU has cleared the `BUSY` bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the `BUSY` bit of the `CANIF2CRQ` register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the `CANIFnCMSK` registers are not evaluated. The message number of the `CANIFnCRQ` registers is also not evaluated. In the `CANIF2MCTL` register, the `NEWDAT` and `MSGLST` bits retain their function, the `DLC[3:0]` field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the `BASIC` bit in the `CANTST` register.

17.3.13.5 Transmit Control

Software can directly override control of the `CANnTX` signal in four different ways.

- `CANnTX` is controlled by the CAN Controller
- The sample point is driven on the `CANnTX` signal to monitor the bit timing
- `CANnTX` drives a low value
- `CANnTX` drives a high value

The last two functions, combined with the readable CAN receive pin CAN_nRX , can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the $TX[1:0]$ field in the **CANTST** register. The three test functions for the CAN_nTX signal interfere with all CAN protocol functions. $TX[1:0]$ must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

17.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

17.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 17-4 on page 1036): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 17-3 on page 1036). The length of the time quantum (t_q), which is the basic time unit of the bit time, is defined by the CAN controller's input clock (f_{SYS}) and the Baud Rate Prescaler (**BRP**):

$$t_q = BRP / f_{sys}$$

The f_{sys} input clock is the system clock frequency as configured by the **RCC** or **RCC2** registers (see page 272 or page 278).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of $Sync$ and the $Sync$ is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 17-4. CAN Bit Time

Table 17-3. CAN Protocol Ranges^a

Parameter	Range	Remark
BRP	[1 .. 64]	Defines the length of the time quantum t _q . The CANBRPE register can be used to extend the range to 1024.
Sync	1 t _q	Fixed length, synchronization of bus input to system clock
Prop	[1 .. 8] t _q	Compensates for the physical delay times
Phase1	[1 .. 8] t _q	May be lengthened temporarily by synchronization
Phase2	[1 .. 8] t _q	May be shortened temporarily by synchronization
SJW	[1 .. 4] t _q	May not be longer than either Phase Buffer Segment

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 17-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 17-4. CANBIT Register Values

CANBIT Register Field	Setting
TSEG2	Phase2 - 1
TSEG1	Prop + Phase1 - 1
SJW	SJW - 1
BRP	BRP

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than $2 t_q$; the CAN's IPT is $0 t_q$. Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

17.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of t_q).

Sync is $1 t_q$ long (fixed), which leaves $(\text{bit time} - \text{Prop} - 1) t_q$ for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, that is, $\text{Phase2} = \text{Phase1}$, else $\text{Phase2} = \text{Phase1} + 1$.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of $[0..2] t_q$.

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- df = Maximum tolerance of oscillator frequency
- f_{osc} = Actual oscillator frequency
- f_{nom} = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(\text{Phase_seg1}, \text{Phase_seg2}) \min}{2 \times (13 \times t_{\text{bit}} - \text{Phase_Seg2})}$$

$$df_{\text{max}} = 2 \times df \times f_{\text{nom}}$$

where:

- Phase1 and Phase2 are from Table 17-3 on page 1036
- tbit = Bit Time
- dfmax = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

17.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E-9} * 25\text{E6} = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of t_q

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (2 * tq) + (1 * tq)
tTSeg1 = 3 * tq

tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 1) * tq
tTSeg2 = 1 * tq                \\Assumes IPT=0

tSJW = 1 * tq                \\Least of 4, Phase1 and Phase2

```

In the above example, the bit field values for the **CANBIT** register are:

TSEG2	= TSeg2 -1 = 1-1 = 0
TSEG1	= TSeg1 -1 = 3-1 = 2
SJW	= SJW -1 = 1-1 = 0
BRP	= Baud rate prescaler - 1 = 5-1 = 4

The final value programmed into the **CANBIT** register = 0x0204.

17.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

```

bit time = 10 μs = n * tq = 10 * tq
tq = 1 μs
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 1E-6 * 50E6 = 50

tSync = 1 * tq = 1 μs                \\fixed at 1 time quanta

delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 μs = 1 * tq                \\1 μs is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 10 * tq
bit time = tSync + tProp + tPhase 1 + tPhase2
tPhase 1 + tPhase2 = bit time - tSync - tProp
tPhase 1 + tPhase2 = (10 * tq) - (1 * tq) - (1 * tq)
tPhase 1 + tPhase2 = 8 * tq
tPhase1 = 4 * tq
tPhase2 = 4 * tq                \\tPhase1 = tPhase2

```

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Assumes IPT}=0 \\
 \\
 tSJW &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Least of 4, Phase1, and Phase2}
 \end{aligned}$$

TSEG2	= TSeg2 -1 = 4-1 = 3
TSEG1	= TSeg1 -1 = 5-1 = 4
SJW	= SJW -1 = 4-1 = 3
BRP	= Baud rate prescaler - 1 = 50-1 =49

The final value programmed into the **CANBIT** register = 0x34F1.

17.4 Register Map

Table 17-5 on page 1040 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 386). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

17.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 * 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is cleared, each time a sequence of 11 High bits has been monitored, a `BITERROR0` code is written to the **CANSTS** register (the `LEC` field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

Value	Description									
0	Normal operation.									
1	Initialization started.									

Register 2: CAN Status (CANSTS), offset 0x004

Important: This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

Bit/Field	Name	Type	Reset	Description
31:15	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	TSEG2	R/W	0x2	Time Segment after Sample Point 0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for <code>Phase2</code> (see Figure 17-4 on page 1036). The bit time quanta is defined by the <code>BRP</code> field.
11:8	TSEG1	R/W	0x3	Time Segment Before Sample Point 0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for <code>Phase1</code> (see Figure 17-4 on page 1036). The bit time quanta is defined by the <code>BRP</code> field.
7:6	SJW	R/W	0x0	(Re)Synchronization Jump Width 0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSEG2</code> or <code>TSEG1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta.
5:0	BRP	R/W	0x1	Baud Rate Prescaler The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum. 0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. <code>BRP</code> defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1). The <code>CANBRPE</code> register can be used to further divide the bit time.

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

Note: Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the `TEST` bit in the `CANCTL` register. Different test functions may be combined, however, CAN transfers are affected if the `TX` bits in this register are not zero.

Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020**Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the CANIF1MCTL register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024

Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028**Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088**

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the **ID** bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

CAN IF1 Mask 1 (CANIF1MSK1)

	Value	Description		
	0	No new data has been written into the data portion of the corresponding message object by the message handler since the last time this flag was cleared by the CPU.		
	1	The message handler or the CPU has written new data into the data portion of the corresponding message object.		

Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140**Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the **INTPND** bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The **INTPND** bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the **INTPND** bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the **INTPND** bits of the second 16 message objects.

18 Universal Serial Bus (USB) Controller

The Stellaris® USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host functions. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. μ DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device startup.

The Stellaris USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
 - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
 - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 2 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size if it is the only endpoint used
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
 - Channel requests asserted when FIFO contains required amount of data

18.1 Block Diagram

Figure 18-1. USB Module Block Diagram

18.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. These signals have dedicated functions and are not alternate functions for any GPIO signals.

Table 18-1. Signals for USB (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
USB0DM	43	PD4	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
USB0DP	44	PD5	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

18.3 Functional Description

The Stellaris USB controller provides the ability for the controller to serve as a Device-only controller. The controller can only be used in Device mode to connect USB-enabled peripherals to the USB controller. For Device mode, the USB controller requires a B connector in the system to provide Device connectivity.

Note: When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz.

18.3.1 Operation

This section describes the Stellaris USB controller's actions. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of Start of Frame (SOF) are all described.

IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB Device. However, in most cases the USB Device should use the dedicated control endpoint on the USB controller's endpoint 0.

18.3.1.1 Endpoints

The USB controller provides two dedicated control endpoints (IN and OUT) and 14 configurable endpoints (7 IN and 7 OUT) that can be used for communications with a Host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining 14 endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as 7 configurable IN and 7 configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

18.3.1.2 IN Transactions

Data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the 7 configurable IN endpoints are determined by the **USB Transmit FIFO Start Address (USBTXFIFOADD)** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USB Maximum Transmit Data Endpoint n (USBTXMAXPn)** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

Note: The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while data is in the FIFO as unexpected results may occur.

Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the **TXRDY** bit in the **USB Transmit Control and Status Endpoint n Low (USBTXCSRLn)** register must be set. If the **AUTOSET** bit in the **USB Transmit Control and Status Endpoint n High (USBTXCSRHn)** register is set, the **TXRDY** bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the **TXRDY** bit must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both **TXRDY** and **FIFONE** are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the **TXRDY** bit in the **USBTXCSRLn** register must be set. If the **AUTOSET** bit in the **USBTXCSRHn** register is set, the **TXRDY** bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, **TXRDY** must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, **TXRDY** is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and **TXRDY** set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, **TXRDY** is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the **FIFONE** bit in the **USBTXCSRLn** register at this point

indicates how many packets may be loaded. If the `FIFONE` bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the `FIFONE` bit is clear, then no packets are in the FIFO and two more packets can be loaded.

Note: Double-packet buffering is disabled if an endpoint's corresponding `EPn` bit is set in the **USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

18.3.1.3 OUT Transactions

OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the 7 configurable OUT endpoints are determined by the **USB Receive FIFO Start Address (USBRXFIFOADD)** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USB Maximum Receive Data Endpoint n (USBRXMAXPn)** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

Note: In all cases, the maximum packet size must not exceed the FIFO size.

Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the `RXRDY` and `FULL` bits in the **USB Receive Control and Status Endpoint n Low (USBRXCSSLn)** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the `RXRDY` bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the `AUTOCL` bit in the **USB Receive Control and Status Endpoint n High (USBRXCSSLn)** register is set and a maximum-sized packet is unloaded from the FIFO, the `RXRDY` and `FULL` bits are cleared automatically. For packet sizes less than the maximum, `RXRDY` must be cleared manually.

Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the `RXRDY` bit in the **USBRXCSSLn** register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

Note: The `FULL` bit in **USBRXCSSLn** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the `RXRDY` bit must be cleared to allow further packets to be received. If the `AUTOCL` bit in the **USBRXCSSLn** register is set and a maximum-sized packet is unloaded from the FIFO, the `RXRDY` bit is cleared automatically. For packet sizes less than the maximum, `RXRDY` must be cleared manually. If the `FULL` bit is set when `RXRDY` is cleared, the USB controller first clears the `FULL` bit, then sets `RXRDY` again to indicate that there is another packet waiting in the FIFO to be unloaded.

Note: Double-packet buffering is disabled if an endpoint's corresponding `EPn` bit is set in the **USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

18.3.1.4 Scheduling

The Device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The Stellaris USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the Device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

18.3.1.5 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the `DATAEND` bit in the **USB Control and Status Endpoint 0 Low (USBCSRL0)** register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared `TXRDY` and set `DATAEND` in response to the ACK issued by the Host to what should have been the last packet.
3. The Host sends more than **USBRXMAXP_n** bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the Device request has been transferred.

However, if the Host sends a zero-length OUT data packet before the entire length of Device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the `DATAEND` bit in the **USBCSRL0** register.

Setting the Device Address

When a Host is attempting to enumerate the USB Device, it requests that the Device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the **USB Device Functional Address (USBFADDR)** register. However, care should be taken when writing to **USBFADDR** to avoid changing the address before the transaction is complete. This register should only be set after the `SET_ADDRESS` command is complete. Like all control transactions, the transaction is only complete after the Device has left the STATUS phase. In the case of a `SET_ADDRESS` command, the transaction is completed by responding to the IN

request from the Host with a zero-byte packet. Once the Device has responded to the IN request, the **USBFADDR** register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

Note: If the **USBFADDR** register is set to the new value as soon as the Device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the Device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the Device.

18.3.1.6 SUSPEND

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the **USB Interrupt Enable (USBIE)** register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the **USB Power (USBPOWER)** register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling.

To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state. The USB controller is not able to Hibernate because all the internal states are lost as a result.

18.3.1.7 Start-of-Frame

When the USB controller is operating in Device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the **USB Frame Value (USBFRAME)** register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the **USBFRAME** register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

18.3.1.8 USB RESET

When a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USB Endpoint Index (USBEPIDX)** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a RESET interrupt.

When the application software driving the USB controller receives a RESET interrupt, any open pipes are closed and the USB controller waits for bus enumeration to begin.

18.3.1.9 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the `SOFTCONN` bit of the **USBPOWER** register. When the `SOFTCONN` bit is set, the PHY is placed in its normal mode, and the `USB0DP/USB0DM` lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET.

When the `SOFTCONN` bit is cleared, the PHY is put into non-driving mode, `USB0DP` and `USB0DM` are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the `SOFTCONN` bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the `SOFTCONN` bit has been set, the USB controller can be disconnected by clearing this bit.

Note: The USB controller does not generate an interrupt when the Device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

18.3.2 DMA Operation

The USB peripheral provides an interface connected to the μ DMA controller with separate channels for 3 transmit endpoints and 3 receive endpoints. Software selects which endpoints to service with the μ DMA channels using the **USB DMA Select (USBDMASEL)** register. The μ DMA operation of the USB is enabled through the **USBTXCSRHn** and **USBRXCSRHn** registers, for the TX and RX channels respectively. When μ DMA operation is enabled, the USB asserts a μ DMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The μ DMA channel must be configured to operate in Basic mode, and the size of the μ DMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using μ DMA must be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the μ DMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If the `DMAMOD` bit in the **USBTXCSRHn/USBRXCSRHn** register is clear, an interrupt is generated after every packet is transferred, but the μ DMA continues transferring data. If the `DMAMOD` bit is set, an interrupt is generated only when the entire μ DMA transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and the μ DMA is enabled, the USB interrupt handler must be designed to handle the μ DMA completion interrupt.

Care must be taken when using the μ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of value of the `MAXLOAD` field in the **USBRXCSRHn** register. The `RXRDY` bit is cleared as follows.

Table 18-2. Remainder (MAXLOAD/4)

Value	Description
0	MAXLOAD = 64 bytes
1	MAXLOAD = 61 bytes
2	MAXLOAD = 62 bytes

Table 18-2. Remainder (MAXLOAD/4) (continued)

Value	Description
3	MAXLOAD = 63 bytes

Table 18-3. Actual Bytes Read

Value	Description
0	MAXLOAD
1	MAXLOAD+3
2	MAXLOAD+2
3	MAXLOAD+1

Table 18-4. Packet Sizes That Clear RXRDY

Value	Description
0	MAXLOAD, MAXLOAD-1, MAXLOAD-2, MAXLOAD-3
1	MAXLOAD
2	MAXLOAD, MAXLOAD-1
3	MAXLOAD, MAXLOAD-1, MAXLOAD-2

To enable DMA operation for the endpoint receive channel, the **DMAEN** bit of the **USBRXCSRHn** register should be set. To enable DMA operation for the endpoint transmit channel, the **DMAEN** bit of the **USBTXCSRHn** register must be set.

See “Micro Direct Memory Access (μ DMA)” on page 581 for more details about programming the μ DMA controller.

18.4 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled via the **RCGCUSB** register (see page 385).

The initial configuration in all cases requires that the processor enable the USB controller and USB controller’s physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY.

The USB controller provides a method to set the current operating mode of the USB controller. This register should be written with the desired default mode so that the controller can respond to external USB events.

18.4.1 Endpoint Configuration

To start communication, the endpoint registers must first be configured. An endpoint must be configured before enumerating to the Host controller.

The endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. The endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. The configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to

1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 2 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

The USB Device controller's soft connect must be enabled when the Device is ready to start communications, indicating to the Host controller that the Device is ready to start the enumeration process.

18.5 Register Map

Table 18-5 on page 1079 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 385). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

18.6 Register Descriptions

The LM4F120B2QR USB controller has Device only capabilities as specified in the USB0 bit field in the DC6 register (see page 249).

Register 1: USB Device Functional Address (USBFADDR), offset 0x000

USBFADDR is an 8-bit register that contains the 7-bit address of the Device part of the transaction.

This register must be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

Important: See the section called “Setting the Device Address” on page 1075 for special considerations when writing this register.

USB Device Functional Address (USBFADDR)

Base 0x4005.0000

Offset 0x000

Type R/W, reset 0x00

	7	6	5	4	3	2	1	0
	reserved	FUNCADDR						
Type	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	FUNCADDR	R/W	0x00	Function Address Function Address of Device as received through SET_ADDRESS.

Register 2: USB Power (USBPOWER), offset 0x001

USBPOWER is an 8-bit register used for controlling SUSPEND and RESUME signaling and some basic operational aspects of the USB controller.

USB Power (USBPOWER)

Base 0x4005.0000
 Offset 0x001
 Type R/W, reset 0x20

	7	6	5	4	3	2	1	0
	ISOUP	SOFTCONN	reserved		RESET	RESUME	SUSPEND	PWRDNPHY
Type	R/W	R/W	RO	RO	RO	R/W	RO	R/W
Reset	0	0	1	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7	ISOUP	R/W	0	<p>Isochronous Update</p> <p>Value Description</p> <p>1 The USB controller waits for an SOF token from the time the TXRDY bit is set in the USBTXCSSLn register before sending the packet. If an IN token is received before an SOF token, then a zero-length data packet is sent.</p> <p>0 No effect.</p> <p>Note: This bit is only valid for isochronous transfers.</p>
6	SOFTCONN	R/W	0	<p>Soft Connect/Disconnect</p> <p>Value Description</p> <p>1 The USB D+/D- lines are enabled.</p> <p>0 The USB D+/D- lines are tri-stated.</p>
5:4	reserved	RO	0x2	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RESET	RO	0	<p>RESET Signaling</p> <p>Value Description</p> <p>1 RESET signaling is present on the bus.</p> <p>0 RESET signaling is not present on the bus.</p>
2	RESUME	R/W	0	<p>RESUME Signaling</p> <p>Value Description</p> <p>1 Enables RESUME signaling when the Device is in SUSPEND mode.</p> <p>0 Ends RESUME signaling on the bus.</p> <p>This bit must be cleared by software 10 ms (a maximum of 15 ms) after being set.</p>

Bit/Field	Name	Type	Reset	Description
1	SUSPEND	RO	0	SUSPEND Mode Value Description 1 The USB controller is in SUSPEND mode. 0 This bit is cleared when software reads the interrupt register or sets the RESUME bit above.
0	PWRDNPHY	R/W	0	Power Down PHY Value Description 1 Powers down the internal USB PHY. 0 No effect.

Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002

Important: This register is read-sensitive. See the register description for details.

USBTXIS is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–7. The meaning of the EP_n bits in this register is based on the mode of the device. The EP_1 through EP_7 bits always indicate that the USB controller is sending data; however, the bits refer to IN endpoints. The EP_0 bit is special and indicates that either a control IN or control OUT endpoint has generated an interrupt.

Note: Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

USB Transmit Interrupt Status (USBTXIS)

Base 0x4005.0000
Offset 0x002
Type RO, reset 0x0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EP7	RO	0	TX Endpoint 7 Interrupt Value Description 0 No interrupt. 1 The Endpoint 7 transmit interrupt is asserted.
6	EP6	RO	0	TX Endpoint 6 Interrupt Same description as EP7.
5	EP5	RO	0	TX Endpoint 5 Interrupt Same description as EP7.
4	EP4	RO	0	TX Endpoint 4 Interrupt Same description as EP7.
3	EP3	RO	0	TX Endpoint 3 Interrupt Same description as EP7.
2	EP2	RO	0	TX Endpoint 2 Interrupt Same description as EP7.
1	EP1	RO	0	TX Endpoint 1 Interrupt Same description as EP7.

Bit/Field	Name	Type	Reset	Description
0	EP0	RO	0	TX and RX Endpoint 0 Interrupt
				Value Description
				0 No interrupt.
				1 The Endpoint 0 transmit and receive interrupt is asserted.

Register 4: USB Receive Interrupt Status (USBRIXIS), offset 0x004

Important: This register is read-sensitive. See the register description for details.

USBRIXIS is a 16-bit read-only register that indicates which of the interrupts for receive endpoints 1–7 are currently active.

Note: Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

USB Receive Interrupt Status (USBRIXIS)

Base 0x4005.0000
Offset 0x004
Type RO, reset 0x0000

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EP7	RO	0	RX Endpoint 7 Interrupt Value Description 0 No interrupt. 1 The Endpoint 7 transmit interrupt is asserted.
6	EP6	RO	0	RX Endpoint 6 Interrupt Same description as EP7.
5	EP5	RO	0	RX Endpoint 5 Interrupt Same description as EP7.
4	EP4	RO	0	RX Endpoint 4 Interrupt Same description as EP7.
3	EP3	RO	0	RX Endpoint 3 Interrupt Same description as EP7.
2	EP2	RO	0	RX Endpoint 2 Interrupt Same description as EP7.
1	EP1	RO	0	RX Endpoint 1 Interrupt Same description as EP7.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006

USBTXIE is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBTXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared, the interrupt in the **USBTXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

USB Transmit Interrupt Enable (USBTXIE)

Base 0x4005.0000

Offset 0x006

Type R/W, reset 0xFFFF

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								EP7	EP6	EP5	EP4	EP3	EP2	EP1	EP0
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EP7	R/W	1	TX Endpoint 7 Interrupt Enable Value Description 1 An interrupt is sent to the interrupt controller when the EP7 bit in the USBTXIS register is set. 0 The EP7 transmit interrupt is suppressed and not sent to the interrupt controller.
6	EP6	R/W	1	TX Endpoint 6 Interrupt Enable Same description as EP7.
5	EP5	R/W	1	TX Endpoint 5 Interrupt Enable Same description as EP7.
4	EP4	R/W	1	TX Endpoint 4 Interrupt Enable Same description as EP7.
3	EP3	R/W	1	TX Endpoint 3 Interrupt Enable Same description as EP7.
2	EP2	R/W	1	TX Endpoint 2 Interrupt Enable Same description as EP7.
1	EP1	R/W	1	TX Endpoint 1 Interrupt Enable Same description as EP7.

Bit/Field	Name	Type	Reset	Description
0	EP0	R/W	1	TX and RX Endpoint 0 Interrupt Enable
				Value Description
				1 An interrupt is sent to the interrupt controller when the EP0 bit in the USBTXIS register is set.
				0 The EP0 transmit and receive interrupt is suppressed and not sent to the interrupt controller.

Register 6: USB Receive Interrupt Enable (USBXIE), offset 0x008

USBXIE is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBXIS** register is set. When a bit is cleared, the interrupt in the **USBXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

USB Receive Interrupt Enable (USBXIE)

Base 0x4005.0000

Offset 0x008

Type R/W, reset 0xFFFE

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								EP7	EP6	EP5	EP4	EP3	EP2	EP1	reserved
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	RO
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	0

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EP7	R/W	1	RX Endpoint 7 Interrupt Enable Value Description 1 An interrupt is sent to the interrupt controller when the EP7 bit in the USBXIS register is set. 0 The EP7 receive interrupt is suppressed and not sent to the interrupt controller.
6	EP6	R/W	1	RX Endpoint 6 Interrupt Enable Same description as EP7.
5	EP5	R/W	1	RX Endpoint 5 Interrupt Enable Same description as EP7.
4	EP4	R/W	1	RX Endpoint 4 Interrupt Enable Same description as EP7.
3	EP3	R/W	1	RX Endpoint 3 Interrupt Enable Same description as EP7.
2	EP2	R/W	1	RX Endpoint 2 Interrupt Enable Same description as EP7.
1	EP1	R/W	1	RX Endpoint 1 Interrupt Enable Same description as EP7.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: USB General Interrupt Status (USBIS), offset 0x00A

Important: This register is read-sensitive. See the register description for details.

USBIS is an 8-bit read-only register that indicates which USB interrupts are currently active. All active interrupts are cleared when this register is read.

USB General Interrupt Status (USBIS)

Base 0x4005.0000
 Offset 0x00A
 Type RO, reset 0x00

	7	6	5	4	3	2	1	0
	reserved	DISCON	reserved	SOF	RESET	RESUME	SUSPEND	
Type	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	DISCON	RO	0	Session Disconnect Value Description 1 The device has been disconnected from the host. 0 No interrupt.
4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SOF	RO	0	Start of Frame Value Description 1 A new frame has started. 0 No interrupt.
2	RESET	RO	0	RESET Signaling Detected Value Description 1 RESET signaling has been detected on the bus. 0 No interrupt.
1	RESUME	RO	0	RESUME Signaling Detected Value Description 1 RESUME signaling has been detected on the bus while the USB controller is in SUSPEND mode. 0 No interrupt.

This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the **USBDRRIS**, **USBDRIM**, and **USBDRISC** registers should be used.

Bit/Field	Name	Type	Reset	Description
0	SUSPEND	RO	0	SUSPEND Signaling Detected
				Value Description
				1 SUSPEND signaling has been detected on the bus.
				0 No interrupt.

Register 8: USB Interrupt Enable (USBIE), offset 0x00B

USBIE is an 8-bit register that provides interrupt enable bits for each of the interrupts in **USBIS**. At reset interrupts 1 and 2 are enabled.

USB Interrupt Enable (USBIE)

Base 0x4005.0000
 Offset 0x00B
 Type R/W, reset 0x06

	7	6	5	4	3	2	1	0
	reserved		DISCON	reserved	SOF	RESET	RESUME	SUSPEND
Type	RO	RO	R/W	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	1	1	0

Bit/Field	Name	Type	Reset	Description
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	DISCON	R/W	0	Enable Disconnect Interrupt Value Description 1 An interrupt is sent to the interrupt controller when the DISCON bit in the USBIS register is set. 0 The DISCON interrupt is suppressed and not sent to the interrupt controller.
4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SOF	R/W	0	Enable Start-of-Frame Interrupt Value Description 1 An interrupt is sent to the interrupt controller when the SOF bit in the USBIS register is set. 0 The SOF interrupt is suppressed and not sent to the interrupt controller.
2	RESET	R/W	1	Enable RESET Interrupt Value Description 1 An interrupt is sent to the interrupt controller when the RESET bit in the USBIS register is set. 0 The RESET interrupt is suppressed and not sent to the interrupt controller.

Bit/Field	Name	Type	Reset	Description
1	RESUME	R/W	1	Enable RESUME Interrupt Value Description 1 An interrupt is sent to the interrupt controller when the RESUME bit in the USBIS register is set. 0 The RESUME interrupt is suppressed and not sent to the interrupt controller.
0	SUSPEND	R/W	0	Enable SUSPEND Interrupt Value Description 1 An interrupt is sent to the interrupt controller when the SUSPEND bit in the USBIS register is set. 0 The SUSPEND interrupt is suppressed and not sent to the interrupt controller.

Register 9: USB Frame Value (USBFRAME), offset 0x00C

USBFRAME is a 16-bit read-only register that holds the last received frame number.

USB Frame Value (USBFRAME)

Base 0x4005.0000
 Offset 0x00C
 Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:11	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:0	FRAME	RO	0x000	Frame Number

Register 10: USB Endpoint Index (USBEPIDX), offset 0x00E

Each endpoint's buffer can be accessed by configuring a FIFO size and starting address. The **USBEPIDX** 8-bit register is used with the **USBTXFIFOSZ**, **USBRXFIFOSZ**, **USBTXFIFOADD**, and **USBRXFIFOADD** registers.

USB Endpoint Index (USBEPIDX)

Base 0x4005.0000
Offset 0x00E
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	EPIDX	R/W	0x0	Endpoint Index This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0x7 corresponds to Endpoint 7.

Register 11: USB Test Mode (USBTEST), offset 0x00F

USBTEST is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for operation described in the *USB 2.0 Specification*, in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

Note: Only one of these bits should be set at any time.

USB Test Mode (USBTEST)

Base 0x4005.0000
 Offset 0x00F
 Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	FIFOACC	R/W1S	0	FIFO Access Value Description 1 Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO. 0 No effect. This bit is cleared automatically.
5	FORCEFS	R/W	0	Force Full-Speed Mode Value Description 1 Forces the USB controller into Full-Speed mode upon receiving a USB RESET. 0 The USB controller operates at Low Speed.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 12: USB FIFO Endpoint 0 (USBFIFO0), offset 0x020

Register 13: USB FIFO Endpoint 1 (USBFIFO1), offset 0x024

Register 14: USB FIFO Endpoint 2 (USBFIFO2), offset 0x028

Register 15: USB FIFO Endpoint 3 (USBFIFO3), offset 0x02C

Register 16: USB FIFO Endpoint 4 (USBFIFO4), offset 0x030

Register 17: USB FIFO Endpoint 5 (USBFIFO5), offset 0x034

Register 18: USB FIFO Endpoint 6 (USBFIFO6), offset 0x038

Register 19: USB FIFO Endpoint 7 (USBFIFO7), offset 0x03C

Important: This register is read-sensitive. See the register description for details.

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see the section called “Single-Packet Buffering” on page 1074). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–7, the associated FIFO is completely flushed.

Register 24: USB Connect Timing (USBCONTIM), offset 0x07A

This 8-bit configuration register specifies connection delay.

USB Connect Timing (USBCONTIM)

Base 0x4005.0000

Offset 0x07A

Type R/W, reset 0x5C

Bit/Field	Name	Type	Reset	Description
7:4	WTCON	R/W	0x5	Connect Wait This field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 μ s.
3:0	WTID	R/W	0xC	Wait ID This field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms.

Register 25: USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF), offset 0x07D

This 8-bit configuration register specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF)

Base 0x4005.0000

Offset 0x07D

Type R/W, reset 0x77

Bit/Field	Name	Type	Reset	Description
7:0	FSEOFG	R/W	0x77	Full-Speed End-of-Frame Gap This field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 μ s.

Register 26: USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF), offset 0x07E

This 8-bit configuration register specifies the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF)

Base 0x4005.0000
 Offset 0x07E
 Type R/W, reset 0x72

Bit/Field	Name	Type	Reset	Description
7:0	LSEOFG	R/W	0x72	<p>Low-Speed End-of-Frame Gap</p> <p>This field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 μs. The default corresponds to 121.6 μs.</p>

Register 27: USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1), offset 0x110

Register 28: USB Maximum Transmit Data Endpoint 2 (USBTXMAXP2), offset 0x120

Register 29: USB Maximum Transmit Data Endpoint 3 (USBTXMAXP3), offset 0x130

Register 30: USB Maximum Transmit Data Endpoint 4 (USBTXMAXP4), offset 0x140

Register 31: USB Maximum Transmit Data Endpoint 5 (USBTXMAXP5), offset 0x150

Register 32: USB Maximum Transmit Data Endpoint 6 (USBTXMAXP6), offset 0x160

Register 33: USB Maximum Transmit Data Endpoint 7 (USBTXMAXP7), offset 0x170

The **USBTXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the `FLUSH` bit in **USBTXCSRLn**) after writing the new value to this register.

Note: **USBTXMAXPn** must be set to an even number of bytes for proper interrupt generation in μ DMA Basic Mode.

USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1)

Base 0x4005.0000
Offset 0x110

Register 35: USB Control and Status Endpoint 0 High (USBCSRH0), offset 0x103

USBSR0H is an 8-bit register that provides control and status bits for endpoint 0.

USB Control and Status Endpoint 0 High (USBCSRH0)

Base 0x4005.0000
 Offset 0x103
 Type W1C, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	FLUSH	R/W	0	Flush FIFO

Value	Description
0	No effect.
1	Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.

This bit is automatically cleared after the flush is performed.

Important: This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

Register 36: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108

USBCOUNT0 is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the `RXRDY` bit is set.

USB Receive Byte Count Endpoint 0 (USBCOUNT0)

2	OVER	R/W	0	<p>Overrun</p> <p>Value Description</p> <p>0 No overrun error.</p> <p>1 Indicates that an OUT packet cannot be loaded into the receive FIFO.</p> <p>Software must clear this bit.</p> <p>Note: This bit is only valid when the endpoint is operating in Isochronous mode. In Bulk mode, it always returns zero.</p>
1	FULL	RO	0	<p>FIFO Full</p> <p>Value Description</p> <p>0 The receive FIFO is not full.</p> <p>1 No more packets can be loaded into the receive FIFO.</p>

Bit/Field	Name	Type	Reset	Description
0	RXRDY	R/W	0	Receive Packet Ready
				Value Description
				0 No data packet has been received.
				1 A data packet has been received. The EP_n bit in the USBXIS register is also set in this situation.
				If the AUTOCLR bit in the USBXCSRHn register is set, then the this bit is automatically cleared when a packet of USBXMAXPn bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.

Register 65: USB Receive Control and Status Endpoint 1 High (USBXCSRH1), offset 0x117

Register 66: USB Receive Control and Status Endpoint 2 High (USBXCSRH2), offset 0x127

Register 67: USB Receive Control and Status Endpoint 3 High (USBXCSRH3), offset 0x137

Register 68: USB Receive Control and Status Endpoint 4 High (USBXCSRH4), offset 0x147

Register 69: USB Receive Control and Status Endpoint 5 High (USBXCSRH5), offset 0x157

Register 70: USB Receive Control and Status Endpoint 6 High (USBXCSRH6), offset 0x167

Register 71: USB Receive Control and Status Endpoint 7 High (USBXCSRH7), offset 0x177

USBXCSRHn is an 8-bit register that provides additional control and status bits for transfers through the currently selected receive endpoint.

USB Receive Control and Status Endpoint 1 High (USBXCSRH1)

Base 0x4005.0000
 Offset 0x117
 Type R/W, reset 0x00

	7	6	5	4	3	2	1	0
	AUTOCL	ISO	DMAEN	DISNYET / PIDERR	DMAMOD	reserved		
Type	R/W	R/W	R/W	R/W	R/W	RO	RO	RO
Reset	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7	AUTOCL	R/W	0	Auto Clear
				Value Description
				0 No effect.
				1 Enables the <code>RXRDY</code> bit to be automatically cleared when a packet of <code>USBXMAXPn</code> bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, <code>RXRDY</code> must be cleared manually. Care must be taken when using μ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the value of the <code>MAXLOAD</code> field in the <code>USBXMAXPn</code> register, see "DMA Operation" on page 1077.
6	ISO	R/W	0	Isochronous Transfers
				Value Description
				0 Enables the receive endpoint for isochronous transfers.
				1 Enables the receive endpoint for bulk/interrupt transfers.

Bit/Field	Name	Type	Reset	Description
5	DMAEN	R/W	0	<p>DMA Request Enable</p> <p>Value Description</p> <p>0 Disables the μDMA request for the receive endpoint.</p> <p>1 Enables the μDMA request for the receive endpoint.</p> <p>Note: 3 TX and 3 RX endpoints can be connected to the μDMA module. If this bit is set for a particular endpoint, the <i>DMAARX</i>, <i>DMABRX</i>, or <i>DMACRX</i> field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.</p>
4	DISNYET / PIDERR	R/W	0	<p>Disable NYET / PID Error</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 <i>For bulk or interrupt transactions:</i> Disables the sending of NYET handshakes. When this bit is set, all successfully received packets are acknowledged, including at the point at which the FIFO becomes full.</p> <p><i>For isochronous transactions:</i> Indicates a PID error in the received packet.</p>
3	DMAMOD	R/W	0	<p>DMA Request Mode</p> <p>Value Description</p> <p>0 An interrupt is generated after every μDMA packet transfer.</p> <p>1 An interrupt is generated only after the entire μDMA transfer is complete.</p> <p>Note: This bit must not be cleared either before or in the same cycle as the above <i>DMAEN</i> bit is cleared.</p>
2:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 72: USB Receive Byte Count Endpoint 1 (USBRXCOUNT1), offset 0x118

Register 73: USB Receive Byte Count Endpoint 2 (USBRXCOUNT2), offset 0x128

Register 74: USB Receive Byte Count Endpoint 3 (USBRXCOUNT3), offset 0x138

Register 75: USB Receive Byte Count Endpoint 4 (USBRXCOUNT4), offset 0x148

Register 76: USB Receive Byte Count Endpoint 5 (USBRXCOUNT5), offset 0x158

Register 77: USB Receive Byte Count Endpoint 6 (USBRXCOUNT6), offset 0x168

Register 78: USB Receive Byte Count Endpoint 7 (USBRXCOUNT7), offset 0x178

Note: The value returned changes as the FIFO is unloaded and is only valid while the `RXRDY` bit in the `USBRXCSRLn` register is set.

`USBRXCOUNTn` is a 16-bit read-only register that holds the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

USB Receive Byte Count Endpoint 1 (USBRXCOUNT1)

19 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

Note: Not all comparators have the option to drive an output pin. See “Signal Description” on page 1130 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris® LM4F120B2QR microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
 - An individual external reference voltage
 - A shared single external reference voltage
 - A shared internal reference voltage

19.1 Block Diagram

Figure 19-1. Analog Comparator Module Block Diagram

19.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 666) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 683) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 645.

Table 19-1. Signals for Analog Comparators (64LQFP)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
C0+	14	PC6	I	Analog	Analog comparator 0 positive input.
C0-	13	PC7	I	Analog	Analog comparator 0 negative input.
C0o	28	PF0 (9)	O	TTL	Analog comparator 0 output.
C1+	15	PC5	I	Analog	Analog comparator 1 positive input.

Table 19-1. Signals for Analog Comparators (64LQFP) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
C1-	16	PC4	I	Analog	Analog comparator 1 negative input.
C1o	29	PF1 (9)	O	TTL	Analog comparator 1 output.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

19.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$$VIN- < VIN+, VOUT = 1$$

$$VIN- > VIN+, VOUT = 0$$

As shown in Figure 19-2 on page 1131, the input source for VIN- is an external input, Cn-. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V_{IREF}.

Figure 19-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the `ISEN` bit in the **ACCTL** register. The output may also be used to drive an external pin, `Co` or generate an analog-to-digital converter (ADC) trigger.

Important: The `ASRCP` bits in the **ACCTL** register must be set before using the analog comparators.

19.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 19-3 on page 1132. The internal reference is controlled by a single configuration register (**ACREFCTL**). Table 19-2 on page 1132 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally (V_{IREF}).

Figure 19-3. Comparator Internal Reference Structure

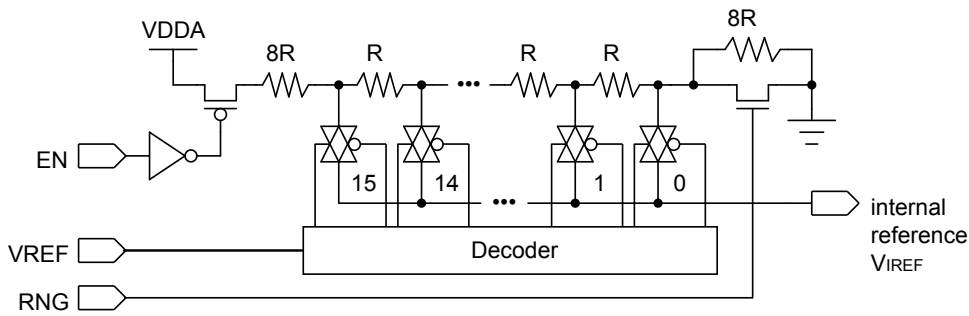

Table 19-2. Internal Reference Voltage and ACREFCTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0	RNG=X	0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.
EN=1	RNG=0	<p>Total resistance in ladder is 31 R.</p> $V_{IREF} = V_{DDA} \times \frac{RV_{REF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{(V_{REF} + 8)}{31}$ $V_{IREF} = 0.85 + 0.106 \times V_{REF}$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p>
	RNG=1	<p>Total resistance in ladder is 23 R.</p> $V_{IREF} = V_{DDA} \times \frac{RV_{REF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{V_{REF}}{23}$ $V_{IREF} = 0.143 \times V_{REF}$ <p>The range of internal reference for this mode is 0-2.152 V.</p>

19.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 388).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 374). To find out which GPIO ports to enable, refer to Table 21-5 on page 1160.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 21-4 on page 1156.
4. Configure the **PMC_n** fields in the **GPIOCTL** register to assign the analog comparator output signals to the appropriate pins (see page 683 and Table 21-5 on page 1160).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTL_n** register with the value of 0x0000.040C.
7. Delay for 10 μ s.
8. Read the comparator output value by reading the **ACSTAT_n** register's **OVAL** value.

Change the level of the comparator negative input signal **C-** to see the **OVAL** value change.

19.5 Register Map

Table 19-3 on page 1133 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 388). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

Table 19-3. Analog Comparators Register Map

Offset	Name	Type	Reset	Description	See page
0x000	ACMIS	R/W1C	0x0000.0000	Analog Comparator Masked Interrupt Status	1135
0x004	ACRIS	RO	0x0000.0000	Analog Comparator Raw Interrupt Status	1136
0x008	ACINTEN	R/W	0x0000.0000	Analog Comparator Interrupt Enable	1137
0x010	ACREFCTL	R/W	0x0000.0000	Analog Comparator Reference Voltage Control	1138
0x020	ACSTAT0	RO	0x0000.0000	Analog Comparator Status 0	1139
0x024	ACCTL0	R/W	0x0000.0000	Analog Comparator Control 0	1140
0x040	ACSTAT1	RO	0x0000.0000	Analog Comparator Status 1	1139
0x044	ACCTL1	R/W	0x0000.0000	Analog Comparator Control 1	1140
0xFC0	ACMPPP	RO	0x0003.0003	Analog Comparator Peripheral Properties	1142

19.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved															IN1	IN0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	R/W1C	0	<p>Comparator 1 Masked Interrupt Status</p> <p>Value Description</p> <p>1 The IN1 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.</p> <p>0 No interrupt has occurred or the interrupt is masked.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the IN1 bit in the ACRIS register.</p>
0	IN0	R/W1C	0	<p>Comparator 0 Masked Interrupt Status</p> <p>Value Description</p> <p>1 The IN0 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.</p> <p>0 No interrupt has occurred or the interrupt is masked.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the IN0 bit in the ACRIS register.</p>

Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000

Offset 0x004

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved															IN1	IN0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	RO	0	<p>Comparator 1 Interrupt Status</p> <p>Value Description</p> <p>1 Comparator 1 has generated an interrupt for an event as configured by the ISEN bit in the ACCTL1 register.</p> <p>0 An interrupt has not occurred.</p> <p>This bit is cleared by writing a 1 to the IN1 bit in the ACMIS register.</p>
0	IN0	RO	0	<p>Comparator 0 Interrupt Status</p> <p>Value Description</p> <p>1 Comparator 0 has generated an interrupt for an event as configured by the ISEN bit in the ACCTL0 register.</p> <p>0 An interrupt has not occurred.</p> <p>This bit is cleared by writing a 1 to the IN0 bit in the ACMIS register.</p>

Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x008

This register provides the interrupt enable for the comparators.

Analog Comparator Interrupt Enable (ACINTEN)

Base 0x4003.C000

Offset 0x008

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	reserved															IN1	IN0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	R/W	0	Comparator 1 Interrupt Enable Value Description 1 The raw interrupt signal comparator 1 is sent to the interrupt controller. 0 A comparator 1 interrupt does not affect the interrupt status.
0	IN0	R/W	0	Comparator 0 Interrupt Enable Value Description 1 The raw interrupt signal comparator 0 is sent to the interrupt controller. 0 A comparator 0 interrupt does not affect the interrupt status.

Register 4: Analog Comparator Reference Voltage Control (ACREFCTL), offset 0x010

This register specifies whether the resistor ladder is powered on as well as the range and tap.

Analog Comparator Reference Voltage Control (ACREFCTL)

Base 0x4003.C000
 Offset 0x010
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	reserved						EN	RNG	reserved					VREF			
Type	RO	RO	RO	RO	RO	RO	R/W	R/W	RO	RO	RO	RO	R/W	R/W	R/W	R/W	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	EN	R/W	0	Resistor Ladder Enable Value Description 0 The resistor ladder is unpowered. 1 Powers on the resistor ladder. The resistor ladder is connected to V_{DDA} . This bit is cleared at reset so that the internal reference consumes the least amount of power if it is not used.
8	RNG	R/W	0	Resistor Ladder Range Value Description 0 The resistor ladder has a total resistance of 31 R. 1 The resistor ladder has a total resistance of 23 R.
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	VREF	R/W	0x0	Resistor Ladder Voltage Ref The V_{REF} bit field specifies the resistor ladder tap that is passed through an analog multiplexer. The voltage corresponding to the tap position is the internal reference voltage available for comparison. See Table 19-2 on page 1132 for some output reference voltage examples.

Register 5: Analog Comparator Status 0 (ACSTAT0), offset 0x020**Register 6: Analog Comparator Status 1 (ACSTAT1), offset 0x040**

These registers specify the current output value of the comparator.

Analog Comparator Status 0 (ACSTAT0)

Base 0x4003.C000

Offset 0x020

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit/Field	Name	Type	Reset	Description
31:19	reserved	-	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
18	C2O	RO	0x0	Comparator Output 2 Present Value Description 1 Comparator output 2 is present. 0 Comparator output 2 is not present.
17	C1O	RO	0x1	Comparator Output 1 Present Value Description 1 Comparator output 1 is present. 0 Comparator output 1 is not present.
16	C0O	RO	0x1	Comparator Output 0 Present Value Description 1 Comparator output 0 is present. 0 Comparator output 0 is not present.
15:3	reserved	-	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	CMP2	RO	0x0	Comparator 2 Present Value Description 1 Comparator 2 is present. 0 Comparator 2 is not present.

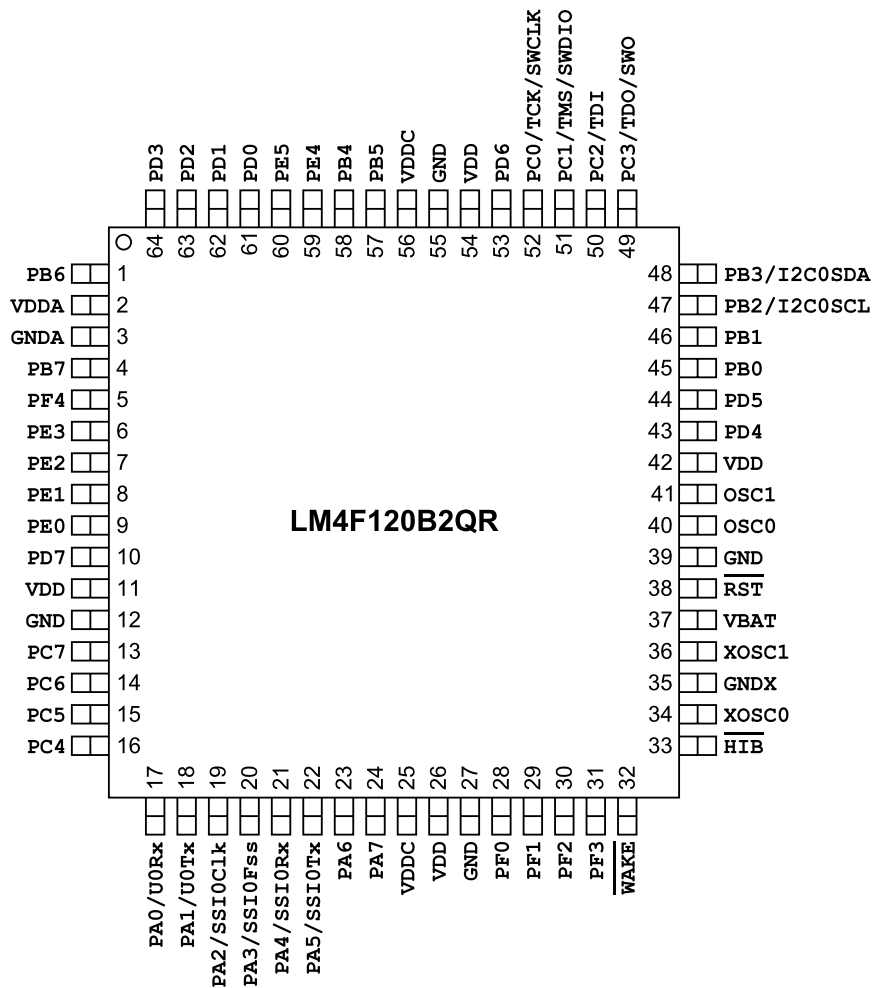

Bit/Field	Name	Type	Reset	Description
1	CMP1	RO	0x1	Comparator 1 Present Value Description 1 Comparator 1 is present. 0 Comparator 1 is not present.
0	CMP0	RO	0x1	Comparator 0 Present Value Description 1 Comparator 0 is present. 0 Comparator 0 is not present.

20 Pin Diagram

The LM4F120B2QR microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 21-5 on page 1160.

Figure 20-1. 64-Pin LQFP Package Pin Diagram

21 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 682) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 666) must be set. Further pin muxing options are provided through the PMC_x bit field in the **GPIOCTL** register (see page 683), which selects one of several available peripheral functions for that GPIO.

Important: All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts the pins back to their default state.

Table 21-1. GPIO Pins With Default Alternate Functions

GPIO Pin	Default State	GPIOAFSEL Bit	GPIOCTL PMC_x Bit Field
PA[1:0]	UART0	0	0x1
PA[5:2]	SSIO	0	0x1
PB[3:2]	I ² C0	0	0x1
PC[3:0]	JTAG/SWD	1	0x3

Table 21-2 on page 1146 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 21-3 on page 1151 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMC_x bit field in the **GPIOCTL** register.

Table 21-4 on page 1156 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 21-5 on page 1160 lists the GPIO pins and their analog and digital alternate functions. The AIN_x analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding $AMSEL$ bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry ($C0-$, $C0+$, $C1-$, $C1+$). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMC_x bit field in the **GPIO Port Control (GPIOCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 21-6 on page 1162 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Stellaris® Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

Note: All digital inputs are Schmitt triggered.

Table 21-2. Signals by Pin Number

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
1	PB6	I/O	TTL	GPIO port B bit 6.
	SSI2Rx	I	TTL	SSI module 2 receive.
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
2	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
3	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
4	PB7	I/O	TTL	GPIO port B bit 7.
	SSI2Tx	O	TTL	SSI module 2 transmit.
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
5	PF4	I/O	TTL	GPIO port F bit 4.
	T2CCP0	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
6	PE3	I/O	TTL	GPIO port E bit 3.
	AIN0	I	Analog	Analog-to-digital converter input 0.
7	PE2	I/O	TTL	GPIO port E bit 2.
	AIN1	I	Analog	Analog-to-digital converter input 1.
8	PE1	I/O	TTL	GPIO port E bit 1.
	AIN2	I	Analog	Analog-to-digital converter input 2.
	U7Tx	O	TTL	UART module 7 transmit.
9	PE0	I/O	TTL	GPIO port E bit 0.
	AIN3	I	Analog	Analog-to-digital converter input 3.
	U7Rx	I	TTL	UART module 7 receive.
10	PD7	I/O	TTL	GPIO port D bit 7.
	NMI	I	TTL	Non-maskable interrupt.
	U2Tx	O	TTL	UART module 2 transmit.
	WT5CCP1	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 1.
11	VDD	-	Power	Positive supply for I/O and some logic.
12	GND	-	Power	Ground reference for logic and I/O pins.
13	PC7	I/O	TTL	GPIO port C bit 7.
	C0-	I	Analog	Analog comparator 0 negative input.
	U3Tx	O	TTL	UART module 3 transmit.
	WT1CCP1	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 1.
14	PC6	I/O	TTL	GPIO port C bit 6.
	C0+	I	Analog	Analog comparator 0 positive input.
	U3Rx	I	TTL	UART module 3 receive.
	WT1CCP0	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 0.

Table 21-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
15	PC5	I/O	TTL	GPIO port C bit 5.
	C1+	I	Analog	Analog comparator 1 positive input.
	U1CTS	I	TTL	UART module 1 Clear To Send modem flow control input signal.
	U1Tx	O	TTL	UART module 1 transmit.
	U4Tx	O	TTL	UART module 4 transmit.
	WT0CCP1	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 1.
16	PC4	I/O	TTL	GPIO port C bit 4.
	C1-	I	Analog	Analog comparator 1 negative input.
	U1RTS	O	TTL	UART module 1 Request to Send modem flow control output line.
	U1Rx	I	TTL	UART module 1 receive.
	U4Rx	I	TTL	UART module 4 receive.
	WT0CCP0	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 0.
17	PA0	I/O	TTL	GPIO port A bit 0.
	U0Rx	I	TTL	UART module 0 receive.
18	PA1	I/O	TTL	GPIO port A bit 1.
	U0Tx	O	TTL	UART module 0 transmit.
19	PA2	I/O	TTL	GPIO port A bit 2.
	SSI0Clk	I/O	TTL	SSI module 0 clock.
20	PA3	I/O	TTL	GPIO port A bit 3.
	SSI0Fss	I/O	TTL	SSI module 0 frame.
21	PA4	I/O	TTL	GPIO port A bit 4.
	SSI0Rx	I	TTL	SSI module 0 receive.
22	PA5	I/O	TTL	GPIO port A bit 5.
	SSI0Tx	O	TTL	SSI module 0 transmit.
23	PA6	I/O	TTL	GPIO port A bit 6.
	I2C1SCL	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
24	PA7	I/O	TTL	GPIO port A bit 7.
	I2C1SDA	I/O	OD	I ² C module 1 data.
25	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
26	VDD	-	Power	Positive supply for I/O and some logic.
27	GND	-	Power	Ground reference for logic and I/O pins.
28	PF0	I/O	TTL	GPIO port F bit 0.
	C0o	O	TTL	Analog comparator 0 output.
	CAN0Rx	I	TTL	CAN module 0 receive.
	NMI	I	TTL	Non-maskable interrupt.
	SSI1Rx	I	TTL	SSI module 1 receive.
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
	TRD2	O	TTL	Trace data 2.
	U1RTS	O	TTL	UART module 1 Request to Send modem flow control output line.

Table 21-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
29	PF1	I/O	TTL	GPIO port F bit 1.
	C1o	O	TTL	Analog comparator 1 output.
	SSI1Tx	O	TTL	SSI module 1 transmit.
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	TRD1	O	TTL	Trace data 1.
	U1CTS	I	TTL	UART module 1 Clear To Send modem flow control input signal.
30	PF2	I/O	TTL	GPIO port F bit 2.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	TRD0	O	TTL	Trace data 0.
31	PF3	I/O	TTL	GPIO port F bit 3.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	SSI1Fss	I/O	TTL	SSI module 1 frame.
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
	TRCLK	O	TTL	Trace clock.
32	$\overline{\text{WAKE}}$	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
33	$\overline{\text{HIB}}$	O	TTL	An output that indicates the processor is in Hibernate mode.
34	XOSC0	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
35	GNDX	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should only be connected to the crystal load capacitors to improve oscillator immunity to system noise. When using an external oscillator, this pin should be connected to GND.
36	XOSC1	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.
37	VBAT	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
38	$\overline{\text{RST}}$	I	TTL	System reset input.
39	GND	-	Power	Ground reference for logic and I/O pins.
40	OSC0	I	Analog	Main oscillator crystal input or an external clock reference input.
41	OSC1	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
42	VDD	-	Power	Positive supply for I/O and some logic.
43	PD4	I/O	TTL	GPIO port D bit 4.
	U6Rx	I	TTL	UART module 6 receive.
	USB0DM	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
	WT4CCP0	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.

Table 21-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
44	PD5	I/O	TTL	GPIO port D bit 5.
	U6Tx	O	TTL	UART module 6 transmit.
	USB0DP	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
	WT4CCP1	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.
45	PB0	I/O	TTL	GPIO port B bit 0. This pin is not 5-V tolerant.
	T2CCP0	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
	U1Rx	I	TTL	UART module 1 receive.
46	PB1	I/O	TTL	GPIO port B bit 1. This pin is not 5-V tolerant.
	T2CCP1	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
	U1Tx	O	TTL	UART module 1 transmit.
47	PB2	I/O	TTL	GPIO port B bit 2.
	I2C0SCL	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	T3CCP0	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
48	PB3	I/O	TTL	GPIO port B bit 3.
	I2C0SDA	I/O	OD	I ² C module 0 data.
	T3CCP1	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
49	PC3	I/O	TTL	GPIO port C bit 3.
	SWO	O	TTL	JTAG TDO and SWO.
	T5CCP1	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
	TDO	O	TTL	JTAG TDO and SWO.
50	PC2	I/O	TTL	GPIO port C bit 2.
	T5CCP0	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
	TDI	I	TTL	JTAG TDI.
51	PC1	I/O	TTL	GPIO port C bit 1.
	SWDIO	I/O	TTL	JTAG TMS and SWDIO.
	T4CCP1	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	TMS	I	TTL	JTAG TMS and SWDIO.
52	PC0	I/O	TTL	GPIO port C bit 0.
	SWCLK	I	TTL	JTAG/SWD CLK.
	T4CCP0	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	TCK	I	TTL	JTAG/SWD CLK.
53	PD6	I/O	TTL	GPIO port D bit 6.
	U2Rx	I	TTL	UART module 2 receive.
	WT5CCP0	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 0.
54	VDD	-	Power	Positive supply for I/O and some logic.
55	GND	-	Power	Ground reference for logic and I/O pins.
56	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.

Table 21-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
57	PB5	I/O	TTL	GPIO port B bit 5.
	AIN11	I	Analog	Analog-to-digital converter input 11.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	SSI2Fss	I/O	TTL	SSI module 2 frame.
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
58	PB4	I/O	TTL	GPIO port B bit 4.
	AIN10	I	Analog	Analog-to-digital converter input 10.
	CAN0Rx	I	TTL	CAN module 0 receive.
	SSI2Clk	I/O	TTL	SSI module 2 clock.
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
59	PE4	I/O	TTL	GPIO port E bit 4.
	AIN9	I	Analog	Analog-to-digital converter input 9.
	CAN0Rx	I	TTL	CAN module 0 receive.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	U5Rx	I	TTL	UART module 5 receive.
60	PE5	I/O	TTL	GPIO port E bit 5.
	AIN8	I	Analog	Analog-to-digital converter input 8.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	U5Tx	O	TTL	UART module 5 transmit.
61	PD0	I/O	TTL	GPIO port D bit 0.
	AIN7	I	Analog	Analog-to-digital converter input 7.
	I2C3SCL	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
	SSI3Clk	I/O	TTL	SSI module 3 clock.
	WT2CCP0	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 0.
62	PD1	I/O	TTL	GPIO port D bit 1.
	AIN6	I	Analog	Analog-to-digital converter input 6.
	I2C3SDA	I/O	OD	I ² C module 3 data.
	SSI1Fss	I/O	TTL	SSI module 1 frame.
	SSI3Fss	I/O	TTL	SSI module 3 frame.
	WT2CCP1	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 1.
63	PD2	I/O	TTL	GPIO port D bit 2.
	AIN5	I	Analog	Analog-to-digital converter input 5.
	SSI1Rx	I	TTL	SSI module 1 receive.
	SSI3Rx	I	TTL	SSI module 3 receive.
	WT3CCP0	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 0.

Table 21-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type ^a	Description
64	PD3	I/O	TTL	GPIO port D bit 3.
	AIN4	I	Analog	Analog-to-digital converter input 4.
	SSI1Tx	O	TTL	SSI module 1 transmit.
	SSI3Tx	O	TTL	SSI module 3 transmit.
	WT3CCP1	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 1.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 21-3. Signals by Signal Name

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
AIN0	6	PE3	I	Analog	Analog-to-digital converter input 0.
AIN1	7	PE2	I	Analog	Analog-to-digital converter input 1.
AIN2	8	PE1	I	Analog	Analog-to-digital converter input 2.
AIN3	9	PE0	I	Analog	Analog-to-digital converter input 3.
AIN4	64	PD3	I	Analog	Analog-to-digital converter input 4.
AIN5	63	PD2	I	Analog	Analog-to-digital converter input 5.
AIN6	62	PD1	I	Analog	Analog-to-digital converter input 6.
AIN7	61	PD0	I	Analog	Analog-to-digital converter input 7.
AIN8	60	PE5	I	Analog	Analog-to-digital converter input 8.
AIN9	59	PE4	I	Analog	Analog-to-digital converter input 9.
AIN10	58	PB4	I	Analog	Analog-to-digital converter input 10.
AIN11	57	PB5	I	Analog	Analog-to-digital converter input 11.
C0+	14	PC6	I	Analog	Analog comparator 0 positive input.
C0-	13	PC7	I	Analog	Analog comparator 0 negative input.
C0o	28	PF0 (9)	O	TTL	Analog comparator 0 output.
C1+	15	PC5	I	Analog	Analog comparator 1 positive input.
C1-	16	PC4	I	Analog	Analog comparator 1 negative input.
C1o	29	PF1 (9)	O	TTL	Analog comparator 1 output.
CAN0Rx	28 58 59	PF0 (3) PB4 (8) PE4 (8)	I	TTL	CAN module 0 receive.
CAN0Tx	31 57 60	PF3 (3) PB5 (8) PE5 (8)	O	TTL	CAN module 0 transmit.
GND	12 27 39 55	fixed	-	Power	Ground reference for logic and I/O pins.
GNDA	3	fixed	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.

Table 21-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
GNDX	35	fixed	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should only be connected to the crystal load capacitors to improve oscillator immunity to system noise. When using an external oscillator, this pin should be connected to GND.
HTB	33	fixed	O	TTL	An output that indicates the processor is in Hibernate mode.
I2C0SCL	47	PB2 (3)	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C0SDA	48	PB3 (3)	I/O	OD	I ² C module 0 data.
I2C1SCL	23	PA6 (3)	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C1SDA	24	PA7 (3)	I/O	OD	I ² C module 1 data.
I2C2SCL	59	PE4 (3)	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C2SDA	60	PE5 (3)	I/O	OD	I ² C module 2 data.
I2C3SCL	61	PD0 (3)	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C3SDA	62	PD1 (3)	I/O	OD	I ² C module 3 data.
NMI	10 28	PD7 (8) PF0 (8)	I	TTL	Non-maskable interrupt.
OSC0	40	fixed	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	41	fixed	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
PA0	17	-	I/O	TTL	GPIO port A bit 0.
PA1	18	-	I/O	TTL	GPIO port A bit 1.
PA2	19	-	I/O	TTL	GPIO port A bit 2.
PA3	20	-	I/O	TTL	GPIO port A bit 3.
PA4	21	-	I/O	TTL	GPIO port A bit 4.
PA5	22	-	I/O	TTL	GPIO port A bit 5.
PA6	23	-	I/O	TTL	GPIO port A bit 6.
PA7	24	-	I/O	TTL	GPIO port A bit 7.
PB0	45	-	I/O	TTL	GPIO port B bit 0. This pin is not 5-V tolerant.
PB1	46	-	I/O	TTL	GPIO port B bit 1. This pin is not 5-V tolerant.
PB2	47	-	I/O	TTL	GPIO port B bit 2.
PB3	48	-	I/O	TTL	GPIO port B bit 3.
PB4	58	-	I/O	TTL	GPIO port B bit 4.
PB5	57	-	I/O	TTL	GPIO port B bit 5.
PB6	1	-	I/O	TTL	GPIO port B bit 6.
PB7	4	-	I/O	TTL	GPIO port B bit 7.

Table 21-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
PC0	52	-	I/O	TTL	GPIO port C bit 0.
PC1	51	-	I/O	TTL	GPIO port C bit 1.
PC2	50	-	I/O	TTL	GPIO port C bit 2.
PC3	49	-	I/O	TTL	GPIO port C bit 3.
PC4	16	-	I/O	TTL	GPIO port C bit 4.
PC5	15	-	I/O	TTL	GPIO port C bit 5.
PC6	14	-	I/O	TTL	GPIO port C bit 6.
PC7	13	-	I/O	TTL	GPIO port C bit 7.
PD0	61	-	I/O	TTL	GPIO port D bit 0.
PD1	62	-	I/O	TTL	GPIO port D bit 1.
PD2	63	-	I/O	TTL	GPIO port D bit 2.
PD3	64	-	I/O	TTL	GPIO port D bit 3.
PD4	43	-	I/O	TTL	GPIO port D bit 4.
PD5	44	-	I/O	TTL	GPIO port D bit 5.
PD6	53	-	I/O	TTL	GPIO port D bit 6.
PD7	10	-	I/O	TTL	GPIO port D bit 7.
PE0	9	-	I/O	TTL	GPIO port E bit 0.
PE1	8	-	I/O	TTL	GPIO port E bit 1.
PE2	7	-	I/O	TTL	GPIO port E bit 2.
PE3	6	-	I/O	TTL	GPIO port E bit 3.
PE4	59	-	I/O	TTL	GPIO port E bit 4.
PE5	60	-	I/O	TTL	GPIO port E bit 5.
PF0	28	-	I/O	TTL	GPIO port F bit 0.
PF1	29	-	I/O	TTL	GPIO port F bit 1.
PF2	30	-	I/O	TTL	GPIO port F bit 2.
PF3	31	-	I/O	TTL	GPIO port F bit 3.
PF4	5	-	I/O	TTL	GPIO port F bit 4.
$\overline{\text{RST}}$	38	fixed	I	TTL	System reset input.
SSI0Clk	19	PA2 (2)	I/O	TTL	SSI module 0 clock.
SSI0Fss	20	PA3 (2)	I/O	TTL	SSI module 0 frame.
SSI0Rx	21	PA4 (2)	I	TTL	SSI module 0 receive.
SSI0Tx	22	PA5 (2)	O	TTL	SSI module 0 transmit.
SSI1Clk	30 61	PF2 (2) PD0 (2)	I/O	TTL	SSI module 1 clock.
SSI1Fss	31 62	PF3 (2) PD1 (2)	I/O	TTL	SSI module 1 frame.
SSI1Rx	28 63	PF0 (2) PD2 (2)	I	TTL	SSI module 1 receive.
SSI1Tx	29 64	PF1 (2) PD3 (2)	O	TTL	SSI module 1 transmit.
SSI2Clk	58	PB4 (2)	I/O	TTL	SSI module 2 clock.
SSI2Fss	57	PB5 (2)	I/O	TTL	SSI module 2 frame.

Table 21-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
SSI2Rx	1	PB6 (2)	I	TTL	SSI module 2 receive.
SSI2Tx	4	PB7 (2)	O	TTL	SSI module 2 transmit.
SSI3Clk	61	PD0 (1)	I/O	TTL	SSI module 3 clock.
SSI3Fss	62	PD1 (1)	I/O	TTL	SSI module 3 frame.
SSI3Rx	63	PD2 (1)	I	TTL	SSI module 3 receive.
SSI3Tx	64	PD3 (1)	O	TTL	SSI module 3 transmit.
SWCLK	52	PC0 (1)	I	TTL	JTAG/SWD CLK.
SWDIO	51	PC1 (1)	I/O	TTL	JTAG TMS and SWDIO.
SWO	49	PC3 (1)	O	TTL	JTAG TDO and SWO.
T0CCP0	1 28	PB6 (7) PF0 (7)	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
T0CCP1	4 29	PB7 (7) PF1 (7)	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
T1CCP0	30 58	PF2 (7) PB4 (7)	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
T1CCP1	31 57	PF3 (7) PB5 (7)	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
T2CCP0	5 45	PF4 (7) PB0 (7)	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
T2CCP1	46	PB1 (7)	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
T3CCP0	47	PB2 (7)	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
T3CCP1	48	PB3 (7)	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
T4CCP0	52	PC0 (7)	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
T4CCP1	51	PC1 (7)	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
T5CCP0	50	PC2 (7)	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
T5CCP1	49	PC3 (7)	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
TCK	52	PC0 (1)	I	TTL	JTAG/SWD CLK.
TDI	50	PC2 (1)	I	TTL	JTAG TDI.
TDO	49	PC3 (1)	O	TTL	JTAG TDO and SWO.
TMS	51	PC1 (1)	I	TTL	JTAG TMS and SWDIO.
TRCLK	31	PF3 (14)	O	TTL	Trace clock.
TRD0	30	PF2 (14)	O	TTL	Trace data 0.
TRD1	29	PF1 (14)	O	TTL	Trace data 1.
TRD2	28	PF0 (14)	O	TTL	Trace data 2.
U0Rx	17	PA0 (1)	I	TTL	UART module 0 receive.
U0Tx	18	PA1 (1)	O	TTL	UART module 0 transmit.
U1CTS	15 29	PC5 (8) PF1 (1)	I	TTL	UART module 1 Clear To Send modem flow control input signal.
U1RTS	16 28	PC4 (8) PF0 (1)	O	TTL	UART module 1 Request to Send modem flow control output line.
U1Rx	16 45	PC4 (2) PB0 (1)	I	TTL	UART module 1 receive.

Table 21-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
U1Tx	15 46	PC5 (2) PB1 (1)	O	TTL	UART module 1 transmit.
U2Rx	53	PD6 (1)	I	TTL	UART module 2 receive.
U2Tx	10	PD7 (1)	O	TTL	UART module 2 transmit.
U3Rx	14	PC6 (1)	I	TTL	UART module 3 receive.
U3Tx	13	PC7 (1)	O	TTL	UART module 3 transmit.
U4Rx	16	PC4 (1)	I	TTL	UART module 4 receive.
U4Tx	15	PC5 (1)	O	TTL	UART module 4 transmit.
U5Rx	59	PE4 (1)	I	TTL	UART module 5 receive.
U5Tx	60	PE5 (1)	O	TTL	UART module 5 transmit.
U6Rx	43	PD4 (1)	I	TTL	UART module 6 receive.
U6Tx	44	PD5 (1)	O	TTL	UART module 6 transmit.
U7Rx	9	PE0 (1)	I	TTL	UART module 7 receive.
U7Tx	8	PE1 (1)	O	TTL	UART module 7 transmit.
USB0DM	43	PD4	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
USB0DP	44	PD5	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
VBAT	37	fixed	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
VDD	11 26 42 54	fixed	-	Power	Positive supply for I/O and some logic.
VDDA	2	fixed	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
VDDC	25 56	fixed	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
$\overline{\text{WAKE}}$	32	fixed	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
WT0CCP0	16	PC4 (7)	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 0.
WT0CCP1	15	PC5 (7)	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 1.
WT1CCP0	14	PC6 (7)	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 0.
WT1CCP1	13	PC7 (7)	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 1.
WT2CCP0	61	PD0 (7)	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 0.
WT2CCP1	62	PD1 (7)	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 1.
WT3CCP0	63	PD2 (7)	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 0.
WT3CCP1	64	PD3 (7)	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 1.
WT4CCP0	43	PD4 (7)	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.
WT4CCP1	44	PD5 (7)	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.

Table 21-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type ^a	Description
WT5CCP0	53	PD6 (7)	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 0.
WT5CCP1	10	PD7 (7)	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 1.
XOSC0	34	fixed	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
XOSC1	36	fixed	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 21-4. Signals by Function, Except for GPIO

Function	Pin Name	Pin Number	Pin Type	Buffer Type ^a	Description
ADC	AIN0	6	I	Analog	Analog-to-digital converter input 0.
	AIN1	7	I	Analog	Analog-to-digital converter input 1.
	AIN2	8	I	Analog	Analog-to-digital converter input 2.
	AIN3	9	I	Analog	Analog-to-digital converter input 3.
	AIN4	64	I	Analog	Analog-to-digital converter input 4.
	AIN5	63	I	Analog	Analog-to-digital converter input 5.
	AIN6	62	I	Analog	Analog-to-digital converter input 6.
	AIN7	61	I	Analog	Analog-to-digital converter input 7.
	AIN8	60	I	Analog	Analog-to-digital converter input 8.
	AIN9	59	I	Analog	Analog-to-digital converter input 9.
	AIN10	58	I	Analog	Analog-to-digital converter input 10.
	AIN11	57	I	Analog	Analog-to-digital converter input 11.
Analog Comparators	C0+	14	I	Analog	Analog comparator 0 positive input.
	C0-	13	I	Analog	Analog comparator 0 negative input.
	C0o	28	O	TTL	Analog comparator 0 output.
	C1+	15	I	Analog	Analog comparator 1 positive input.
	C1-	16	I	Analog	Analog comparator 1 negative input.
	C1o	29	O	TTL	Analog comparator 1 output.
Controller Area Network	CAN0Rx	28 58 59	I	TTL	CAN module 0 receive.
	CAN0Tx	31 57 60	O	TTL	CAN module 0 transmit.
	TRCLK	31	O	TTL	Trace clock.
	TRD0	30	O	TTL	Trace data 0.
Core	TRD1	29	O	TTL	Trace data 1.
	TRD2	28	O	TTL	Trace data 2.

Table 21-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type ^a	Description
General-Purpose Timers	T0CCP0	1 28	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
	T0CCP1	4 29	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	T1CCP0	30 58	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	T1CCP1	31 57	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
	T2CCP0	5 45	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
	T2CCP1	46	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
	T3CCP0	47	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
	T3CCP1	48	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
	T4CCP0	52	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	T4CCP1	51	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	T5CCP0	50	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
	T5CCP1	49	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
	WT0CCP0	16	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 0.
	WT0CCP1	15	I/O	TTL	32/64-Bit Wide Timer 0 Capture/Compare/PWM 1.
	WT1CCP0	14	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 0.
	WT1CCP1	13	I/O	TTL	32/64-Bit Wide Timer 1 Capture/Compare/PWM 1.
	WT2CCP0	61	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 0.
	WT2CCP1	62	I/O	TTL	32/64-Bit Wide Timer 2 Capture/Compare/PWM 1.
	WT3CCP0	63	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 0.
	WT3CCP1	64	I/O	TTL	32/64-Bit Wide Timer 3 Capture/Compare/PWM 1.
WT4CCP0	43	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.	
WT4CCP1	44	I/O	TTL	32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.	
WT5CCP0	53	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 0.	
WT5CCP1	10	I/O	TTL	32/64-Bit Wide Timer 5 Capture/Compare/PWM 1.	

Table 21-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type ^a	Description
Hibernate	GNDX	35	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should only be connected to the crystal load capacitors to improve oscillator immunity to system noise. When using an external oscillator, this pin should be connected to GND.
	HTB	33	O	TTL	An output that indicates the processor is in Hibernate mode.
	VBAT	37	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
	WAKE	32	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
	XOSC0	34	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
	XOSC1	36	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.
I2C	I2C0SCL	47	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C0SDA	48	I/O	OD	I ² C module 0 data.
	I2C1SCL	23	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C1SDA	24	I/O	OD	I ² C module 1 data.
	I2C2SCL	59	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C2SDA	60	I/O	OD	I ² C module 2 data.
	I2C3SCL	61	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C3SDA	62	I/O	OD	I ² C module 3 data.
JTAG/SWD/SWO	SWCLK	52	I	TTL	JTAG/SWD CLK.
	SWDIO	51	I/O	TTL	JTAG TMS and SWDIO.
	SWO	49	O	TTL	JTAG TDO and SWO.
	TCK	52	I	TTL	JTAG/SWD CLK.
	TDI	50	I	TTL	JTAG TDI.
	TDO	49	O	TTL	JTAG TDO and SWO.
	TMS	51	I	TTL	JTAG TMS and SWDIO.

Table 21-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type ^a	Description
Power	GND	12 27 39 55	-	Power	Ground reference for logic and I/O pins.
	GNDA	3	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	VDD	11 26 42 54	-	Power	Positive supply for I/O and some logic.
	VDDA	2	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
	VDDC	25 56	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
SSI	SSI0Clk	19	I/O	TTL	SSI module 0 clock.
	SSI0Fss	20	I/O	TTL	SSI module 0 frame.
	SSI0Rx	21	I	TTL	SSI module 0 receive.
	SSI0Tx	22	O	TTL	SSI module 0 transmit.
	SSI1Clk	30 61	I/O	TTL	SSI module 1 clock.
	SSI1Fss	31 62	I/O	TTL	SSI module 1 frame.
	SSI1Rx	28 63	I	TTL	SSI module 1 receive.
	SSI1Tx	29 64	O	TTL	SSI module 1 transmit.
	SSI2Clk	58	I/O	TTL	SSI module 2 clock.
	SSI2Fss	57	I/O	TTL	SSI module 2 frame.
	SSI2Rx	1	I	TTL	SSI module 2 receive.
	SSI2Tx	4	O	TTL	SSI module 2 transmit.
	SSI3Clk	61	I/O	TTL	SSI module 3 clock.
	SSI3Fss	62	I/O	TTL	SSI module 3 frame.
SSI3Rx	63	I	TTL	SSI module 3 receive.	
SSI3Tx	64	O	TTL	SSI module 3 transmit.	
System Control & Clocks	NMI	10 28	I	TTL	Non-maskable interrupt.
	OSC0	40	I	Analog	Main oscillator crystal input or an external clock reference input.
	OSC1	41	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
	RST	38	I	TTL	System reset input.

Table 21-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type ^a	Description
UART	U0Rx	17	I	TTL	UART module 0 receive.
	U0Tx	18	O	TTL	UART module 0 transmit.
	U1CTS	15 29	I	TTL	UART module 1 Clear To Send modem flow control input signal.
	U1RTS	16 28	O	TTL	UART module 1 Request to Send modem flow control output line.
	U1Rx	16 45	I	TTL	UART module 1 receive.
	U1Tx	15 46	O	TTL	UART module 1 transmit.
	U2Rx	53	I	TTL	UART module 2 receive.
	U2Tx	10	O	TTL	UART module 2 transmit.
	U3Rx	14	I	TTL	UART module 3 receive.
	U3Tx	13	O	TTL	UART module 3 transmit.
	U4Rx	16	I	TTL	UART module 4 receive.
	U4Tx	15	O	TTL	UART module 4 transmit.
	U5Rx	59	I	TTL	UART module 5 receive.
	U5Tx	60	O	TTL	UART module 5 transmit.
	U6Rx	43	I	TTL	UART module 6 receive.
	U6Tx	44	O	TTL	UART module 6 transmit.
	U7Rx	9	I	TTL	UART module 7 receive.
U7Tx	8	O	TTL	UART module 7 transmit.	
USB	USB0DM	43	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
	USB0DP	44	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 21-5. GPIO Pins and Alternate Functions

21.1 Connections for Unused Signals

Table 21-7 on page 1164 shows how to handle signals for functions that are not used in a particular system implementation for devices that are in a 64-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 21-7. Connections for Unused Signals (64-Pin LQFP)

Function	Signal Name	Pin Number	Acceptable Practice	Preferred Practice
GPIO	All unused GPIOs	-	NC	GND
Hibernate	HTB	33	NC	NC
	VBAT	37	NC	VDD
	$\overline{\text{WAKE}}$	32	NC	GND
	XOSC0	34	NC	GND
	XOSC1	36	NC	NC
	GNDX	35	GND	GND
No Connects	NC	-	NC	NC
System Control	OSC0	40	NC	GND
	OSC1	41	NC	NC
	$\overline{\text{RST}}$	38	Pull up as shown in Figure 5-1 on page 209	Connect through a capacitor to GND as close to pin as possible

Table 21-7. Connections for Unused Signals (64-Pin LQFP) (continued)

Function	Signal Name	Pin Number	Acceptable Practice	Preferred Practice
USB	USB0DM	43	NC	GND
	USB0DP	44	NC	GND

22 Operating Characteristics

Table 22-1. Temperature Characteristics

Characteristic	Symbol	Value	Unit
Industrial operating temperature range	T_A	-40 to +85	°C
Unpowered storage temperature range	T_S	-65 to +150	°C

Table 22-2. Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) ^a	Θ_{JA}	50 ^b	°C/W
Junction temperature, -40 to +125 ^c	T_J	$T_A + (P \cdot \Theta_{JA})$	°C
Maximum power dissipation	P	560 ^d	mW

a. Junction to ambient thermal resistance Θ_{JA} numbers are determined by a package simulator.

b. Preliminary.

c. Power dissipation is a function of temperature.

d. Preliminary, pending characterization.

Table 22-3. ESD Absolute Maximum Ratings^a

Parameter Name	Min	Nom	Max	Unit
V_{ESDHBM}	-	-	2.0	kV
V_{ESDCDM}	-	-	500	V

a. All Stellaris[®] parts are ESD tested following the JEDEC standard.

23 Electrical Characteristics

23.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

Note: The device is not guaranteed to operate properly at the maximum ratings.

Table 23-1. Maximum Ratings

Parameter	Parameter Name ^a	Value		Unit
		Min	Max	
V _{DD}	V _{DD} supply voltage	0	4	V
V _{DDA}	V _{DDA} supply voltage	0	4	V
V _{BAT}	V _{BAT} battery supply voltage	0	4	V
V _{IN}	Input voltage ^b	-0.3	5.5	V
	Input voltage for PB0 and PB1 when configured as GPIO	-0.3	V _{DD} + 0.3	V
I _{GPIO MAX}	Maximum current per output pin	-	25	mA
I _{NON}	Maximum current into or out of a non-power pin when the microcontroller is unpowered	-	pending ^c	mA

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

c. Pending characterization.

Important: This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1164).

23.2 Recommended Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V_{OL} value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

Table 23-2. Recommended DC Operating Conditions

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{DD}	V _{DD} supply voltage	2.97	3.3	3.63	V
V _{DDA}	V _{DDA} supply voltage	2.97	3.3	3.63	V
V _{DDC}	V _{DDC} supply voltage	1.08	1.2	1.32	V
V _{IH}	High-level input voltage	2.1	-	5.0	V

Table 23-2. Recommended DC Operating Conditions (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{IL}	Low-level input voltage	-0.3	-	1.2	V
V_{OH}	High-level output voltage	2.4	-	-	V
V_{OL}	Low-level output voltage	-	-	0.4	V
I_{OH}	High-level source current, $V_{OH}=2.4$ V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
I_{OL}	Low-level sink current, $V_{OL}=0.4$ V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
	8-mA Drive, $V_{OL}=1.2$ V	18.0	-	-	mA

Table 23-3. GPIO Current Restrictions

Parameter	Parameter Name	Min	Nom	Max	Unit
I_{MAXL}	Cumulative maximum GPIO current per side, left ^a	-	-	30 ^b	mA
I_{MAXB}	Cumulative maximum GPIO current per side, bottom ^a	-	-	35 ^b	mA
I_{MAXR}	Cumulative maximum GPIO current per side, right ^a	-	-	40 ^b	mA
I_{MAXT}	Cumulative maximum GPIO current per side, top ^a	-	-	40 ^b	mA

a. Sum of sink and source current for GPIOs as shown in Table 23-4 on page 1168.

b. Preliminary, pending characterization.

Table 23-4. GPIO Package Side Assignments

Side	GPIOs
Left	PB[6-7], PC[4-7], PD7, PE[0-3], PF4
Bottom	PA[0-7], PF[0-3]
Right	PB[0-3], PD[4-5]
Top	PB[4-5], PC[0-3], PD[0-3,6], PE[4-5]

23.3 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

Figure 23-1. Load Conditions

23.4 JTAG and Boundary Scan

Table 23-5. JTAG Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
J1	F_{TCK}	TCK operational clock frequency ^a	0	-	10	MHz
J2	T_{TCK}	TCK operational clock period	100	-	-	ns
J3	T_{TCK_LOW}	TCK clock Low time	-	t_{TCK}	-	ns
J4	T_{TCK_HIGH}	TCK clock High time	-	t_{TCK}	-	ns
J5	T_{TCK_R}	TCK rise time	0	-	10	ns
J6	T_{TCK_F}	TCK fall time	0	-	10	ns
J7	T_{TMS_SU}	TMS setup time to TCK rise	8	-	-	ns
J8	T_{TMS_HLD}	TMS hold time from TCK rise	4	-	-	ns
J9	T_{TDI_SU}	TDI setup time to TCK rise	18	-	-	ns
J10	T_{TDI_HLD}	TDI hold time from TCK rise	4	-	-	ns
J11	T_{TDO_ZDV}	TCK fall to Data Valid from High-Z, 2-mA drive	-	13	35	ns
		TCK fall to Data Valid from High-Z, 4-mA drive		9	26	ns
		TCK fall to Data Valid from High-Z, 8-mA drive		8	26	ns
		TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control		10	29	ns
J12	T_{TDO_DV}	TCK fall to Data Valid from Data Valid, 2-mA drive	-	14	20	ns
		TCK fall to Data Valid from Data Valid, 4-mA drive		10	26	ns
		TCK fall to Data Valid from Data Valid, 8-mA drive		8	21	ns
		TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control		10	26	ns
J13	T_{TDO_DVZ}	TCK fall to High-Z from Data Valid, 2-mA drive	-	7	16	ns
		TCK fall to High-Z from Data Valid, 4-mA drive		7	16	ns
		TCK fall to High-Z from Data Valid, 8-mA drive		7	16	ns
		TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control		8	19	ns

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

Figure 23-2. JTAG Test Clock Input Timing

Figure 23-3. JTAG Test Access Port (TAP) Timing

23.5 Power and Brown-Out

Table 23-6. Power Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
P1	$T_{VDDRISE}$	Supply voltage (V_{DD}) rise time	-	-	∞	ms
P2	V_{TH}	Power-On Reset threshold (rising edge)	pending ^a	2.92 ^b	pending	V
		Power-On Reset threshold (falling edge)	pending	2.35 ^b	pending	V
P3	V_{BTH}	Brown-Out Reset threshold (rising edge)	pending	2.92 ^b	pending	V
		Brown-Out Reset threshold (falling edge)	pending	2.92 ^b	pending	V
P4	T_{POR}	Power-On Reset timeout	-	-	500	μ s
P5	T_{BOR}	Brown-Out Reset timeout	1	-	- ^c	μ s

a. Pending characterization.

b. Preliminary, pending characterization.

c. After the minimum timeout, BOR stays active as long as the power supply is below V_{BTH} . The voltage level is checked every clock cycle after the initial countdown completes. BOR is deasserted on the next clock cycle after the BOR condition goes away.

Figure 23-4. Power-On and Brown-Out Reset and Voltage Parameters

Figure 23-5. Brown-Out Reset Timing

23.6 Reset

Table 23-7. Reset Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
R1	T_{IRHWR}	Internal reset timeout after hardware reset (RST pin)	20	-	- ^a	μs
R2	T_{IRSWR}	Internal reset timeout after software-initiated system reset	-	1	-	μs
R3	T_{IRWDR}	Internal reset timeout after watchdog reset	-	1	-	μs
R4	T_{IRMFR}	Internal reset timeout after MOSC failure reset	-	1	-	μs

Table 23-7. Reset Characteristics (continued)

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
R5	T_{MIN}	Minimum \overline{RST} pulse width	100	-	-	ns

a. After the minimum timeout, internal reset stays active as long as the \overline{RST} pin is asserted, and is released when the \overline{RST} pin is deasserted.

Figure 23-6. External Reset Timing (\overline{RST})

Figure 23-7. Software Reset Timing

Figure 23-8. Watchdog Reset Timing

Figure 23-9. MOSC Failure Reset Timing

23.7 On-Chip Low Drop-Out (LDO) Regulator

Table 23-8. LDO Regulator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
C_{LDO}	External filter capacitor size for internal power supply ^a	2.5	-	4.0	μF
ESR	Filter capacitor equivalent series resistance	10	-	100	$\text{m}\Omega$

Table 23-8. LDO Regulator Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
ESL	Filter capacitor equivalent series inductance	-	-	0.5	nH
V _{LDO}	LDO output voltage	1.08	1.2	1.32	V
I _{INRUSH}	Inrush current	50	-	250	mA

a. The capacitor should be connected as close as possible to pin 56.

23.8 Clocks

The following sections provide specifications on the various clock sources and mode.

23.8.1 PLL Specifications

The following tables provide specifications for using the PLL.

Table 23-9. Phase Locked Loop (PLL) Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{REF_XTAL}	Crystal reference	5 ^a	-	25	MHz
F _{REF_EXT}	External clock reference ^a	5 ^a	-	25	MHz
F _{PLL}	PLL frequency ^b	-	400	-	MHz
T _{READY}	PLL lock time, enabling the PLL	-	-	512 * (N+1) ^c	reference clocks ^d
	PLL lock time, changing the XTAL field in the RCC/RCC2 register or changing the OSCSRC between MOSC and PIOSC	-	-	128 * (N+1) ^c	reference clocks ^d

a. If the PLL is not used, the minimum input frequency can be 4 MHz.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

c. N is the value in the N field in the **PLLREQ1** register.

d. A reference clock is the clock period of the crystal being used, which can be MOSC or PIOSC. For example, a 16-MHz crystal connected to MOSC yields a reference clock of 62.5 ns.

Table 23-10 on page 1173 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

Table 23-10. Actual PLL Frequency

XTAL	Crystal Frequency (MHz)	MINT	MFRAC	Q	N	PLL Multiplier	PLL Frequency (MHz)	Error
0x09	5.0	0x50	0x0	0x0	0x0	80	400	-
0x0A	5.12	0x9C	0x100	0x0	0x1	156.25	400	-
0x0B	6.0	0xC8	0x0	0x0	0x2	200	400	-
0x0C	6.144	0xC3	0x140	0x0	0x2	195.3125	400	-
0x0D	7.3728	0xA2	0x30A	0x0	0x2	162.7598	399.9984	0.0004%
0x0E	8.0	0x32	0x0	0x0	0x0	50	400	-
0x0F	8.192	0xC3	0x140	0x0	0x3	195.3125	400	-
0x10	10.0	0x50	0x0	0x0	0x1	80	400	-
0x11	12.0	0xC8	0x0	0x0	0x5	200	400	-
0x12	12.288	0xC3	0x140	0x0	0x5	195.3125	400	-
0x13	13.56	0xB0	0x3F6	0x0	0x5	176.9902	399.9979	0.0005%

Table 23-10. Actual PLL Frequency (continued)

XTAL	Crystal Frequency (MHz)	MINT	MFRAC	Q	N	PLL Multiplier	PLL Frequency (MHz)	Error
0x14	14.318	0xC3	0x238	0x0	0x6	195.5547	399.9982	0.0005%
0x15	16.0	0x32	0x0	0x0	0x1	50	400	-
0x16	16.384	0xC3	0x140	0x0	0x7	195.3125	400	-
0x17	18	0xC8	0x0	0x0	0x8	200	400	-
0x18	20	0x50	0x0	0x0	0x3	80	400	-
0x19	24	0x32	0x0	0x0	0x2	50	400	-
0x1A	25	0x50	0x0	0x0	0x4	80	400	-

23.8.2 PIOSC Specifications

Table 23-11. PIOSC Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{PIOSC25}	Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C	-	±0.25% ^a	±1% ^a	-
F _{PIO SCT}	Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C, across specified temperature range	-	-	±3% ^a	-
F _{PIO SCUCAL}	Internal 16-MHz precision oscillator frequency variance, user calibrated at a chosen temperature	-	±0.25% ^a	±1% ^a	-

a. Preliminary, pending characterization.

23.8.3 Internal 30-kHz Oscillator Specifications

Table 23-12. 30-kHz Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{IOSC30KHZ}	Internal 30-KHz oscillator frequency	10 ^a	30	50 ^a	KHz

a. Preliminary, pending characterization.

23.8.4 Hibernation Clock Source Specifications

Table 23-13. HIB Oscillator Input Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{HIBOSC}	Parallel resonance frequency	-	32.768	-	KHz
C ₁ , C ₂	External load capacitance on XOSC0, XOSC1 pins ^a	12	-	24	pF
C _{PKG}	Device package stray shunt capacitance ^a	-	0.5	-	pF
C _{PCB}	PCB stray shunt capacitance ^a	-	0.5	-	pF
C ₀	Crystal shunt capacitance ^a	-	3	-	pF
C _{SHUNT}	Total shunt capacitance ^a	-	-	4	pF
ESR	Crystal effective series resistance, OSCDRV = 0 ^b	-	-	50	kΩ
	Crystal effective series resistance, OSCDRV = 1 ^b	-	-	75	kΩ
DL	Oscillator output drive level	-	-	0.25	μW
T _{START}	Oscillator startup time, when using a crystal ^c	-	600	pending ^d	ms

Table 23-13. HIB Oscillator Input Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{IH}	CMOS input high level, when using an external oscillator ^e	Supply - 0.4	-	Supply	V
V _{IL}	CMOS input low level, when using an external oscillator	GND	-	GND + 0.4	V
V _{HYS}	CMOS input buffer hysteresis, when using an external oscillator	-	600	-	mV
DC _{HIBOSC_EXT}	External clock reference duty cycle	45	-	55	%

a. See information below table.

b. Crystal ESR specified by crystal manufacturer.

c. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

d. Pending characterization.

e. Maximum V_{IH} is relative to the larger of V_{DD} or V_{BAT}.

The load capacitors added on the board, C₁ and C₂, should be chosen such that the following equation is satisfied (see Table 23-13 on page 1174 for typical values).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- C_{SHUNT} = C_{PKG} + C_{PCB} + C₀ (total shunt capacitance seen across XOSC0, XOSC1)
- C_{PKG}, C_{PCB} as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for C_{1,2} ≤ 18 pF; set the OSCDRV bit for C_{1,2} > 18 pF.
- C₀ = Shunt capacitance of crystal specified by the crystal manufacturer

23.8.5 Main Oscillator Specifications

Table 23-14. Main Oscillator Input Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{MOSC}	Parallel resonance frequency	4 ^a	-	25	MHz
C ₁ , C ₂	External load capacitance on OSC0, OSC1 pins ^b	12	-	24	pF
C _{PKG}	Device package stray shunt capacitance ^b	-	0.5	-	pF
C _{PCB}	PCB stray shunt capacitance ^b	-	0.5	-	pF
C ₀	Crystal shunt capacitance ^{bc}	-	4	-	pF
C _{SHUNT}	Total shunt capacitance ^b	-	-	4	pF
ESR	Crystal effective series resistance, 4 MHz ^{dc}	-	-	300	Ω
	Crystal effective series resistance, 6 MHz ^{dc}	-	-	200	Ω
	Crystal effective series resistance, 8 MHz ^{dc}	-	-	130	Ω
	Crystal effective series resistance, 12 MHz ^{dc}	-	-	120	Ω
	Crystal effective series resistance, 16 MHz ^{dc}	-	-	100	Ω
	Crystal effective series resistance, 25 MHz ^{dc}	-	-	50	Ω
DL	Oscillator output drive level ^e	-	-	OSC _{PWR}	mW

Table 23-14. Main Oscillator Input Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
T _{START}	Oscillator startup time, when using a crystal ^f	-	-	18	ms
V _{IH}	CMOS input high level, when using an external oscillator	0.65 * V _{DD}	-	V _{DD}	V
V _{IL}	CMOS input low level, when using an external oscillator	GND	-	0.35 * V _{DD}	V
V _{HYS}	CMOS input buffer hysteresis, when using an external oscillator	150	-	-	mV
DC _{HIBOSC_EXT}	External clock reference duty cycle	45	-	55	%

a. 5 MHz is the minimum when using the PLL.

b. See information below table.

c. Crystal vendors can be contacted to confirm these specifications are met for a specific crystal part number if the vendors generic crystal datasheet show limits outside of these specifications.

d. Crystal ESR specified by crystal manufacturer.

e. $OSC_{PWR} = (2 * \pi * F_P * C_L * 2.5)^2 * ESR / 2$. MOSC is capable of supplying over 1 mW of power. The maximum power delivered to the crystal is based on the C_L, F_P and ESR parameters of the crystal in the circuit as calculated by the OSC_{PWR} equation. Ensure that the value calculated for OSC_{PWR} does not exceed the crystal's drive-level maximum.

f. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board, C₁ and C₂, should be chosen such that the following equation is satisfied (see Table 23-14 on page 1175 for typical values).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{STRAY}$
- C_{STRAY} = C_{PKG} + C_{PCB} (equivalent shunt cap as seen by the oscillator)
- C_{PKG}, C_{PCB} = Shunt capacitance between XOSC0, XOSC1 due to package and boardPCB stray parasitics
- C₀ = Shunt capacitance of crystal specified by the crystal manufacturer

Table 23-15. Supported MOSC Crystal Frequencies^a

Value	Crystal Frequency (MHz) Not Using the PLL	Crystal Frequency (MHz) Using the PLL
0x00-0x5	reserved	
0x06	4 MHz	reserved
0x07	4.096 MHz	reserved
0x08	4.9152 MHz	reserved
0x09	5 MHz (USB)	
0x0A	5.12 MHz	
0x0B	6 MHz (USB)	
0x0C	6.144 MHz	
0x0D	7.3728 MHz	
0x0E	8 MHz (USB)	
0x0F	8.192 MHz	
0x10	10.0 MHz (USB)	
0x11	12.0 MHz (USB)	

Table 23-15. Supported MOSC Crystal Frequencies (continued)

Value	Crystal Frequency (MHz) Not Using the PLL	Crystal Frequency (MHz) Using the PLL
0x12		12.288 MHz
0x13		13.56 MHz
0x14		14.31818 MHz
0x15		16.0 MHz (reset value)(USB)
0x16		16.384 MHz
0x17		18.0 MHz (USB)
0x18		20.0 MHz (USB)
0x19		24.0 MHz (USB)
0x1A		25.0 MHz (USB)

a. Frequencies that may be used with the USB interface are indicated in the table.

23.8.6 System Clock Specification with ADC Operation

Table 23-16. System Clock Characteristics with ADC Operation

Parameter	Parameter Name	Min	Nom	Max	Unit
F_{sysadc}	System clock frequency when the ADC module is operating (when PLL is bypassed). ^a	15.9952	16	16.0048	MHz

a. Clock frequency (plus jitter) must be stable inside specified range. ADC can be clocked from the PLL, directly from an external clock source, or from the PIOSC, as long as frequency absolute precision is inside specified range.

23.8.7 System Clock Specification with USB Operation

Table 23-17. System Clock Characteristics with USB Operation

Parameter	Parameter Name	Min	Nom	Max	Unit
F_{sysusb}	System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL)	30	-	-	MHz

23.9 Sleep Modes

Table 23-18. Sleep Modes AC Characteristics^a

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
D1	$T_{\text{WAKE_S}}$	Time to wake from interrupt in sleep mode ^b	-	-	2	system clocks
	$T_{\text{WAKE_DS}}$	Time to wake from interrupt in deep-sleep mode, using PIOSC for both Run mode and Deep-sleep mode ^{bc}	-	1.25	-	μs
		Time to wake from interrupt in deep-sleep mode, using PIOSC for Run mode and IOSC for Deep-sleep mode mode ^{cb}	-	350	-	μs
D2	$T_{\text{WAKE_PLL_DS}}$	Time to wake from interrupt in deep-sleep mode when using the PLL ^b	-	-	T_{READY}	ms

a. Values in this table assume the IOSC is the clock source during sleep or deep-sleep mode.

b. Specified from registering the interrupt to first instruction.

c. If the main oscillator is used for run mode, add the main oscillator startup time, T_{START} .

23.10 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 495.

Table 23-19. Hibernation Module Battery Characteristics

Parameter	Parameter Name	Min	Nominal	Max	Unit
V _{BAT}	Battery supply voltage	1.8	3.0	3.6	V
V _{LOWBAT}	Low battery detect voltage, VBATSEL=0x0	1.85	1.9	1.95	V
	Low battery detect voltage, VBATSEL=0x1	2.05	2.1	2.15	V
	Low battery detect voltage, VBATSEL=0x2	2.25	2.3	2.35	V
	Low battery detect voltage, VBATSEL=0x3	2.45	2.5	2.55	V

Table 23-20. Hibernation Module AC Characteristics

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
H1	T _{WAKE}	$\overline{\text{WAKE}}$ assertion time	100	-	-	ns
H2	T _{WAKE_TO_HIB}	$\overline{\text{WAKE}}$ assert to $\overline{\text{HIB}}$ desassert (wake up time)	-	-	31	μs
H3	T _{VDD_RAMP}	V _{DD} ramp to 3.0 V	-	Depends on characteristics of power supply	-	μs
H4	T _{VDD_CODE}	V _{DD} at 3.0 V to internal POR deassert; first instruction executes	-	-	500	μs

Figure 23-10. Hibernation Module Timing

23.11 Flash Memory and EEPROM

Table 23-21. Flash Memory Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
PE _{CYC}	Number of guaranteed program/erase cycles before failure ^a	100,000	-	-	cycles
T _{RET}	Data retention, -40°C to +85°C	10	-	-	years
T _{PROG64}	Program time for double-word-aligned 64 bits of data ^b	30	50	150 ^c	µs
T _{ERASE}	Page erase time, <1k cycles endurance	2	25	-	ms
	Page erase time, 100k cycles endurance	-	-	100 ^c	ms
T _{ME}	Mass erase time, <1k cycles endurance	70	200	-	ms
	Mass erase time, 100k cycles endurance	-	-	900	ms

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

c. The memory controller will complete the operation within this specified maximum. It is possible under extreme conditions on previous endurance cycling that a verification failure flag will be issued upon completion. In the event that this flag is generated, issue the same operation again to extend the high-voltage operation.

Table 23-22. EEPROM Characteristics^a

Parameter	Parameter Name	Min	Nom	Max	Unit
EPE _{CYC}	Number of guaranteed mass program/erase cycles of a single word before failure ^b	500,000	-	-	cycles
ET _{RET}	Data retention, -40°C to +85°C	10	-	-	years
ET _{PROG}	Program time for 32 bits of data - space available	-	110	600	µs
	Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and less than 10% of EEPROM endurance used	-	30	-	ms
	Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and greater than 90% of EEPROM endurance used	-	-	900	ms
	Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and less than 10% of EEPROM endurance used	-	60	-	ms
	Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and greater than 90% of EEPROM endurance used	-	-	1800	ms
ET _{READ}	Read access time	-	4	-	system clocks
ET _{ME}	Mass erase time, <1k cycles endurance	70	200	-	ms
	Mass erase time, 100k cycles endurance	-	-	900	ms

a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.

b. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

23.12 GPIO Module

Note: All GPIOs are 5-V tolerant, except PB0 and PB1. See “Signal Description” on page 645 for more information on GPIO configuration.

Table 23-23. GPIO Module Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
R _{GPIOU}	GPIO internal pull-up resistor	13	20	30	kΩ
R _{GPIOPD}	GPIO internal pull-down resistor	13	20	35	kΩ
I _{LKG}	GPIO input leakage current, V _{IN} = 3.3 V ± 10% ^a	-	-	1.0	μA
	GPIO input leakage current, V _{IN} = 5.0 V _{IN} ± 10% ^a	-	-	60	μA
T _{GPIOR}	GPIO Rise Time, 2-mA drive ^b	-	14 ^c	pending ^d	ns
	GPIO Rise Time, 4-mA drive ^b		6 ^c	pending	ns
	GPIO Rise Time, 8-mA drive ^b		4 ^c	pending	ns
	GPIO Rise Time, 8-mA drive with slew rate control ^b		5 ^c	pending	ns
T _{GPIOF}	GPIO Fall Time, 2-mA drive ^e	-	20 ^c	pending	ns
	GPIO Fall Time, 4-mA drive ^e		9 ^c	pending	ns
	GPIO Fall Time, 8-mA drive ^e		4 ^c	pending	ns
	GPIO Fall Time, 8-mA drive with slew rate control ^e		6 ^c	pending	ns

a. The leakage current is measured with GND or VDD applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pullup/pulldown resistor is disabled.

b. Time measured from 20% to 80% of V_{DD}.

c. Preliminary, pending characterization.

d. Pending characterization.

e. Time measured from 80% to 20% of V_{DD}.

23.13 Analog-to-Digital Converter (ADC)

Table 23-24. ADC Electrical Characteristics^a

Parameter	Parameter Name	Min	Nom	Max	Unit
POWER SUPPLY REQUIREMENTS					
V _{DDA}	ADC supply voltage	2.9	3.3	3.6	V
G _{DA}	ADC ground voltage	-	0	-	V
VDDA / G _{DA} VOLTAGE REFERENCE					
C _{REF}	Voltage reference decoupling capacitance	-	0.1 // 0.01 ^b	-	μF
ANALOG INPUT					
V _{ADCIN}	Single-ended, full-scale analog input voltage, internal reference ^{cd}	0	-	V _{DDA}	V
	Differential, full-scale analog input voltage, internal reference ^{ce}	-V _{DDA}	-	V _{DDA}	V
I _L	ADC input leakage current ^f	-	-	2.0	μA
R _{ADC}	ADC equivalent input resistance ^f	-	-	2.5	kΩ
C _{ADC}	ADC equivalent input capacitance ^f	-	-	10	pF
R _S	Analog source resistance ^f	-	-	500	Ω
SAMPLING DYNAMICS					
F _{ADC}	ADC conversion clock frequency ^g	-	16	-	MHz
F _{CONV}	ADC conversion rate	1			MSPS
T _S	ADC sample time	-	250	-	ns
T _C	ADC conversion time	1			μs

Table 23-24. ADC Electrical Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
T_{LT}	Latency from trigger to start of conversion	-	2	-	ADC clocks
SYSTEM PERFORMANCE ^{hi}					
N	Resolution	12			bits
INL	Integral nonlinearity error, over full input range	-	±1.5	pending ^j	LSB
DNL	Differential nonlinearity error, over full input range	-	±0.8	±1.0	LSB
E_O	Offset error	-	±1.0	pending	LSB
E_G	Gain error ^k	-	±2.0	pending	LSB
E_T	Total unadjusted error, over full input range ^l	-	±3.5	pending	LSB
TEMPERATURE SENSOR					
V_{TSENS}	Temperature sensor voltage, junction temperature 25 °C	-	1.633	-	V
S_{TSENS}	Temperature sensor slope, ambient temperature -40 °C to 85 °C	-	-13.3	-	mV/°C
E_{TSENS}	Temperature sensor accuracy, ambient temperature -40 °C to 85 °C ^m	-	-	±5	°C

a. At ambient temperature= -40 °C to 85 °C, V_{REF} = 3.3V, F_{ADC} =16 MHz unless otherwise noted.

b. Two capacitors in parallel.

c. Internal reference is connected directly between V_{DDA} and $GNDA$ ($V_{REFI} = V_{DDA} - GNDA$). Dynamic characteristics cannot be ensured when internal reference is used due to potential high noise coupling through V_{DDA} . Use only when data can be averaged over many samples. Internal reference voltage is selected when V_{REF} field in the **ADCCTL** register is 0x0.

d. $V_{ADCIN} = V_{INP} - V_{INN}$

e. With signal common mode as $V_{DDA}/2$.

f. As shown in Figure 23-11 on page 1182, R_{ADC} is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.

g. See "System Clock Specification with ADC Operation" on page 1177 for full ADC clock frequency specification.

h. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.

i. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.

j. Pending characterization.

k. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.

l. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.

m. Note that this parameter does not include ADC error.

Figure 23-11. ADC Input Equivalency Diagram

23.14 Synchronous Serial Interface (SSI)

Table 23-25. SSI Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S1	T_{CLK_PER}	SSIClk cycle time ^a	40	-	-	ns
S2	T_{CLK_HIGH}	SSIClk high time	-	0.5	-	t clk_per
S3	T_{CLK_LOW}	SSIClk low time	-	0.5	-	t clk_per
S4	T_{CLKRF}	SSIClk rise/fall time ^b	-	4	pending ^c	ns
S5	T_{DMD}	Data from master valid delay time	0	-	1	system clocks
S6	T_{DMS}	Data from master setup time	1	-	-	system clocks
S7	T_{DMH}	Data from master hold time	2	-	-	system clocks
S8	T_{DSS}	Data from slave setup time	1	-	-	system clocks
S9	T_{DSH}	Data from slave hold time	2	-	-	system clocks

a. In master mode, the system clock must be at least twice as fast as the SSIClk; in slave mode, the system clock must be at least 6 times faster than the SSIClk.

b. Note that the delays shown are using 8-mA drive strength.

c. Pending characterization.

Figure 23-12. SSI Timing for TI Frame Format (FRF=01), Single Transfer Timing Measurement

Figure 23-13. SSI Timing for MICROWIRE Frame Format (FRF=10), Single Transfer

Figure 23-14. SSI Timing for SPI Frame Format (FRF=00), with SPH=1

23.15 Inter-Integrated Circuit (I²C) Interface

Table 23-26. I²C Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
11 ^a	T _{SCH}	Start condition hold time	36	-	-	system clocks
12 ^a	T _{LP}	Clock Low period	36	-	-	system clocks
13 ^b	T _{SRT}	I ² C _{SCL} /I ² C _{SDA} rise time (V _{IL} =0.5 V to V _{IH} =2.4 V)	-	-	(see note b)	ns
14 ^a	T _{DH}	Data hold time	2	-	-	system clocks
15 ^c	T _{SFT}	I ² C _{SCL} /I ² C _{SDA} fall time (V _{IH} =2.4 V to V _{IL} =0.5 V)	-	9	10	ns
16 ^a	T _{HT}	Clock High time	24	-	-	system clocks
17 ^a	T _{DS}	Data setup time	18	-	-	system clocks
18 ^a	T _{SCSR}	Start condition setup time (for repeated start condition only)	36	-	-	system clocks
19 ^a	T _{SCS}	Stop condition setup time	24	-	-	system clocks

- a. Values depend on the value programmed into the TPR bit in the I²C Master Timer Period (I²C_{MTPR}) register; a TPR programmed for the maximum I²C_{SCL} frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I²C interface is designed to scale the actual data transition time to move it to the middle of the I²C_{SCL} Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I²C_{SCL} and I²C_{SDA} are open-drain-type outputs, which the controller can only actively drive Low, the time I²C_{SCL} or I²C_{SDA} takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

Figure 23-15. I²C Timing

23.16 Universal Serial Bus (USB) Controller

The Stellaris® USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support). Some components of the USB system are integrated within the LM4F120B2QR microcontroller and specific to the Stellaris microcontroller design.

23.17 Analog Comparator

Table 23-27. Analog Comparator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{INP}, V_{INN}	Input voltage range	GNDA	-	V_{DDA}	V
V_{CM}	Input common mode voltage range	GNDA	-	V_{DDA}	V
V_{OS}	Input offset voltage	-	± 10	pending ^a	mV
I_{INP}, I_{INN}	Input leakage current over full voltage range	-	-	2.0	μA
C_{MRR}	Common mode rejection ratio	-	50	-	dB
T_{RT}	Response time	-	-	1	μs
T_{MC}	Comparator mode change to Output Valid	-	-	10	μs

a. Pending characterization.

Table 23-28. Analog Comparator Voltage Reference Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
R_{HR}	Resolution high range	-	$V_{DDA}/31$	-	V
R_{LR}	Resolution low range	-	$V_{DDA}/23$	-	V
A_{HR}	Absolute accuracy high range, $LSB = V_{DDA}/31$	-	-	$\pm 1/2$	LSB
A_{LR}	Absolute accuracy low range, $LSB = V_{DDA}/23$	-	-	$\pm 1/4$	LSB

23.18 Current Consumption

23.18.1 Preliminary Current Consumption

The following table provides preliminary figures for current consumption while ongoing characterization is completed.

Table 23-29. Preliminary Current Consumption

Parameter	Parameter Name	Conditions	Nom	Max	Unit
I_{DD_RUN}	Run mode 1 (Flash loop)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All ON System Clock = 80 MHz (with PLL) Temp = 25°C	50	-	mA
	Run mode 1 (SRAM loop)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All ON System Clock = 80 MHz (with PLL) Temp = 25°C	40	-	mA
	Run mode 2 (Flash loop)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = 80 MHz (with PLL) Temp = 25°C	30	-	mA
	Run mode 2 (SRAM loop)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = 80 MHz (with PLL) Temp = 25°C	20	-	mA
I_{DD_SLEEP}	Sleep mode	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = 80 MHz (with PLL) Temp = 25°C	12	-	mA
		$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = 16 MHz (with PIOSC) ^b Temp = 25°C	4.5	-	mA
		$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = 1 MHz (with PIOSC/16) ^b Temp = 25°C	3.8	-	mA

Table 23-29. Preliminary Current Consumption (continued)

Parameter	Parameter Name	Conditions	Nom	Max	Unit
I _{DD_DEEPSLEEP}	Deep-sleep mode	V _{DD} = 3.3 V V _{DDA} = 3.3 V Test Configuration: Typical system configuration ^a Peripherals = All OFF System Clock = IOS30KHZ Temp = 25°C	pending ^c	-	μA
I _{HIB_NORTC}	Hibernate mode (external wake, RTC disabled)	V _{BAT} = 3.0 V V _{DD} = 0 V V _{DDA} = 0 V Test Configuration: Typical system configuration ^a System Clock = OFF Hibernate Module = 32.768 kHz	1.6	-	μA
I _{HIB_RTC}	Hibernate mode (RTC enabled)	V _{BAT} = 3.0 V V _{DD} = 0 V V _{DDA} = 0 V Test Configuration: Typical system configuration ^a System Clock = OFF Hibernate Module = 32.768 kHz	1.7	-	μA
I _{HIB_VDD3ON}	Hibernate mode (VDD3ON mode)	V _{BAT} = 3.0 V V _{DD} = 3.3 V V _{DDA} = 3.3 V Test Configuration: Typical system configuration ^a System Clock = OFF Hibernate Module = 32.768 kHz	5.0	-	μA

a. Will be updated with specific details upon further characterization.

b. Note that if the MOSC is the source of the Run-mode system clock and is powered down in Sleep mode, wake time is increased by T_{MOSC_SETTLE}.

c. Pending characterization.

B Ordering and Contact Information

B.1 Ordering Information

Table B-1. Part Ordering Information

Orderable Part Number	Description
LM4F120B2QRFIG	Stellaris® LM4F120B2QR Microcontroller Industrial Temperature 64-pin LQFP
LM4F120B2QRFIGR	Stellaris LM4F120B2QR Microcontroller Industrial Temperature 64-pin LQFP Tape-and-reel

B.2 Part Markings

The Stellaris microcontrollers are marked with an identifying number. This code contains the following information:

- The first and second lines indicate the part number. For example, LM4F232H5QDFIGA0. The second letter in the part number indicates the product status. An M indicates the part is fully qualified and released to production. An X, for example, LX4F232H5QDFIGA0, indicates the part is experimental and requires a waiver
- The third line contains internal tracking numbers.

B.3 Kits

The Stellaris Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the website at www.ti.com/stellaris for the latest tools available, or ask your distributor.

B.4 Support Information

For support on Stellaris products, contact the TI Worldwide Product Information Center nearest you:
<http://www-k.ext.ti.com/sc/technical-support/product-information-centers.htm>.

C Package Information

C.1 64-Pin LQFP Package

C.1.1 Package Dimensions

Figure C-1. Stellaris LM4F120B2QR 64-Pin LQFP Package

MTQF008A – JANUARY 1995 – REVISED DECEMBER 1996

PM (S-PQFP-G64)

PLASTIC QUAD FLATPACK

- NOTES: A. All linear dimensions are in millimeters.
 B. This drawing is subject to change without notice.
 C. Falls within JEDEC MS-026
 D. May also be thermally enhanced plastic with leads connected to the die pads.

PACKAGING INFORMATION

Orderable Device	Status ⁽¹⁾	Package Type	Package Drawing	Pins	Package Qty	Eco Plan ⁽²⁾	Lead/ Ball Finish	MSL Peak Temp ⁽³⁾	Samples (Requires Login)
LM4F120B2QRFIGR	PREVIEW	LQFP	PM	64	1500	TBD	Call TI	Call TI	

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
