SYNCHRONOUS BUCK CONTROLLER WITH HIGH-CURRENT GATE DRIVER

Check for Samples :TPS51113 TPS51163

FEATURES

- **Flexible Power Rails: 5 V to 12 V**
- **Reference: 800 mV ± 0.8%**
- **Voltage Mode Control**
- **Support Pre-biased Startup**
- **Programmable Overcurrent Protection with Low-Side $R_{DS(on)}$ Current Sensing**
- **Fixed 300-kHz (TPS51113) and 600-kHz (TPS51163) Switching Frequency**
- **UV/OV Protections and Power Good Indicator**
- **Internal Soft-start**
- **Integrated High-Current Drivers Powered by VDD**
- **10-Pin 3 × 3 SON Package**

APPLICATIONS

- **Server and Desktop Computer Subsystem Power Supplies (MCH, IOCH, PCI, Termination)**
- **Distributed Power Supplies**
- **General DC-DC Converters**

DESCRIPTION

The TPS51113 and TPS51163 are cost-optimized, feature rich, single-channel synchronous-buck controllers that operates from a single 4.5-V to 13.2-V supply and can convert an input voltage as low as 1.5 V.

The controller implements voltage mode control with a fixed 300-kHz (TPS51113) and 600-kHz (TPS51163) switching frequency. The overcurrent (OC) protection employs the low-side $R_{DS(on)}$ current sensing and has user-programmable threshold. The OC threshold is set by the resistor from LDRV_OC pin to GND. The resistor value is read when the over-current programming circuit applies 10 µA of current to the LDRV_OC pin during the calibration phase of the start-up sequence.

The TPS51113/TPS51163 also supports output pre-biased startup.

The integrated gate driver is directly powered by VDD. VDD can be connected to V_{IN} in some applications. The strong gate drivers with low deadtime allow for the utilization of larger MOSFETs to achieve higher efficiency. An adaptive anti-cross conduction scheme is used to prevent shoot-through between the power FETs.

TERMINAL INFORMATION

TERMINAL FUNCTIONS

TERMINAL		I/O	DESCRIPTION
NAME	PIN NO.		
BOOT	1	I	Gate drive voltage for the high-side N-channel MOSFET. Typically, a 100 nF capacitor must be connected between this pin and SW. Also, a diode from VDD to BOOT should be externally provided.
COMP_EN	7	I/O	Output of the error amplifier and the shutdown pin. Pulling the voltage on this pin lower than 800 mV shuts the controller down.
FB	8	I	Inverting input to the error amplifier. In normal operation, the voltage on this pin is equal to the internal reference voltage of 800 mV.
GND	5	–	Common reference for the device.
HDRV	3	O	Gate drive output for the high-side N-channel MOSFET.
LDRV_OC	4	O	Gate drive output for the low-side or rectifier MOSFET. The set point is read during start up calibration with the 10 µA current source present.
PGOOD	10	O	Open drain power good output. An external pull-up resistor is required.
SW	2	O	Sense line for the adaptive anti-cross conduction circuitry. Serves as common connection for the flying high-side FET driver.
VDD	6	I	Power input to the controller, 4.5 V to 13.2 V.
VOS	9	I	Input to set undervoltage and overvoltage protections. Undervoltage protection occurs when VOS voltage is lower than 600 mV. The controller shuts down with both MOSFETs latched off. Overvoltage protection occurs when VOS voltage is higher than 1V, the upper MOSFET is turned off and the lower MOSFET is forced on until VOS voltage reaches 400 mV. Then the lower MOSFET is also turned off. After the undervoltage or overvoltage events, normal operation can be restored only by cycling the VDD voltage.

DETAILED DESCRIPTION

TPS51113 and TPS51163 are cost-optimized, single channel synchronous buck controllers that operate at a 300-kHz (TPS51113) and 600-kHz (TPS51163) fixed switching frequency, from a single 4.5-V to 13.2-V supply, and supports output pre-biased startup. The overcurrent protection uses the low-side $R_{DS(on)}$ current sensing for a low-cost, loss-less solution. Other features include input undervoltage lockout (UVLO), programmable overcurrent threshold, soft-start, output oververvoltage/undervoltage (OV/UV) protection. The integrated gate driver is powered directly by VDD. This makes the gate drive voltage more flexible.

SOFT START AND SELF-CALIBRATION

When VDD is above 4.3 V and the COMP_EN pin is released from being pulled low with open-drain system logic, the controller enters the start-up sequence. There is a two stage start-up sequence for the COMP_EN voltage. In the first phase of start-up (t_{SS_delay}), the controller completes self-calibration and inhibits FET switching, leaving both the upper and lower MOSFETs in the off state. In the second phase of start-up (t_{SS}), soft-start begins and switching is enabled. The internal reference gradually rises to 800 mV, and the output voltage gets within its regulation point. The soft-start time (t_{SS}) is internally programmed at 3.5 ms, and t_{SS_Delay} is programmed at 5.5 ms. On average, it takes approximately 9 ms for the output voltage to come into regulation after the COMP_EN pin is released.

Figure 7 shows the typical startup and shutdown sequence. The overcurrent protection is enabled when the soft-start begins and the soft-start voltage exceeds the pre-biased VOS voltage. The output overvoltage protection is enabled approximately 64 clock cycles after the COMP pin voltage rises above 0.8 V (thereby enabling the device). When the soft-start ends, the output undervoltage protection is enabled, and PGOOD signal also goes high at the same time.

Figure 7. Typical Startup and Shutdown Sequence

OVERCURRENT PROTECTION

Overcurrent detection is done by comparing a user programmable threshold with the voltage drop across the low-side FET at the end of the switching period (The low-side FET is on). The OC threshold is set with a single external resistor connected from the LDRV_OC pin to GND.

The overcurrent programming circuit applies 10-µA of current to the LDRV_OC pin during the calibration phase of the start-up sequence. Voltage drop on the LDRV_OC pin is measured and digitized, and the related code is stored in the internal latch. This code determines a reference level for the overcurrent comparator. The value of the OC set resistor R_{OCSET} can be determined in Equation 1.

$$R_{OCSET} = \frac{R_{LDS(on)} \times \left(I_{OC} - \frac{I_{RIPPLE}}{2} \right)}{10\,\mu A}$$

(1)

where

- $R_{LDS(on)}$ is the drain-to-source resistance of the lower MOSFET in the ON state
- I_{OC} is the desired value of the overcurrent protection threshold for load current
- I_{RIPPLE} is the peak-to-peak amplitude of the inductor ripple current
- the valley of the inductor current is compared with the overcurrent threshold for protection

When the controller senses the overcurrent condition for more than two clock cycles, both the upper and the lower MOSFETs are latched off. To restart the controller, the VDD input should be cycled.

If the overcurrent set resistor value is higher than 50 kΩ, for example, the voltage drop on the LDRV_OC pin exceeds 0.5 V, the controller stays in the calibration state without entering soft-start. This prevents the controller from being activated if the overcurrent set resistor is missing.

OVERVOLTAGE (OV) AND UNDERVOLTAGE (UV) PROTECTION

The controller employs the dedicated VOS input to set output undervoltage and overvoltage protections. A resistor divider with the same ratio as on the FB input is recommended for the VOS input. The overvoltage and undervoltage thresholds for VOS are set to ± 25% of the internal reference, which is 800 mV.

When the voltage on VOS is lower than 600 mV, the undervoltage protection is triggered. The controller is latched off with both the upper and lower MOSFETs turned off.

When the voltage on VOS is higher than 1 V, the overvoltage protection is activated. In the event of overvoltage, the upper MOSFET is turned off and the lower MOSFET is forced on until VOS voltage reaches 400 mV. Then the lower MOSFET is also turned off, and the controller is latched off.

After both the undervoltage and overvoltage events, normal operation can only be restored by cycling the VDD voltage.

PGOOD

The TPS51113 and TPS51163 have a power good output that indicates HIGH when the output voltage is within the target range. The PGOOD function is activated as soon as the soft-start ends. When the output voltage goes ± 10% outside of the target value, PGOOD goes low. When the output voltage returns to be within ± 6% of the target value, PGOOD signal goes HIGH again. The PGOOD output is an open drain and needs external pull up resistor.

APPLICATION INFORMATION

EXTERNAL PARTS SELECTION

CHOOSING THE INDUCTOR

The value of the output filtering inductor determines the magnitude of the current ripple, which also affects the output voltage ripple for a certain output capacitance value. Increasing the inductance value reduces the ripple current, and thus, results in reduced conduction loss and output ripple voltage. On the other hand, low inductance value is needed due to the demand of low profile and fast transient response. Therefore, it is important to obtain a compromise between the low ripple current and low inductance value.

In practical application, to ensure high power conversion efficiency at light load condition, the peak-to-peak current ripple is usually designed to be between 1/4 to 1/2 of the rated load current. Since the magnitude of the current ripple is determined by inductance value, switching frequency, input voltage and output voltage, the required inductance value for a certain required ripple ΔI is shown in Equation 2,

$$L = \frac{(V_{IN} - V_{OUT}) \times V_{OUT}}{V_{IN} \times I_{RIPPLE} \times f_{SW}}$$

(2)

where

- V_{IN} is the input voltage
- V_{OUT} is the output voltage
- I_{RIPPLE} is the required current ripple
- f_{SW} is the switching frequency

CALCULATING OUTPUT CAPACITANCE

When the inductance value is determined, the output capacitance value can also be derived according to the output ripple voltage and output load transient response requirement. The output ripple voltage is a function of both the output capacitance and capacitor ESR. Considering the worst case and assume the capacitance value is C_{OUT}, the peak-to-peak ripple voltage can be derived in Equation 3.

$$\Delta V = I_{RIPPLE} \times \left(ESR + \frac{1}{8 \times C_{OUT} \times f_{SW}} \right)$$

(3)

Thus, output capacitors with suitable ESR and capacitance value should be chosen to meet the ripple voltage (ΔV) requirement.

Minimum capacitance value is also calculated according to the demand of the load transient response. When the load current changes, the energy that the inductor needs to release or absorb is derived in Equation 4.

$$E_L = \frac{1}{2} \times L \times \left((I_{OH})^2 - (I_{OL})^2 \right)$$

(4)

At the same time, the energy that is delivered to or provided by the output capacitor can also be derived as shown in Equation 5.

$$E_C = \frac{1}{2} \times C_{OUT} \times \left((Vf)^2 - (Vi)^2 \right)$$

(5)

As a result, to meet the load transient response demand, the minimum output capacitance should be

$$C_{OUT} = \frac{L \times \left((I_{OH})^2 - (I_{OL})^2\right)}{\left|(V_f)^2 - (V_i)^2\right|}$$

(6)

where

- I_{OH} is the output current under heavy load conditions
- I_{OL} is the output current under light load conditions
- V_f is the final peak capacitor voltage
- V_i is the initial capacitor voltage

By considering the demand of both output ripple voltage and load transient response, the minimum output capacitance can be determined.

INPUT CAPACITOR SELECTION

For a certain rated load current, input and output voltage, the input ripple voltage caused by the input capacitance value and ESR are shown in Equation 7 and Equation 8, respectively.

$$V_{RIPPLE}(C_{IN}) = \frac{I_{OUT} \times V_{OUT}}{C_{IN(min)} \times V_{IN} \times f_{SW}}$$

(7)

$$V_{RIPPLE}(ESR\_C_{IN}) = ESR_{C_{IN}} \times \left(I_{OUT} + \frac{1}{2} \times I_{RIPPLE}\right)$$

(8)

Based on the required input voltage ripple, suitable capacitors can be chosen by using the above equations.

CHOOSING MOSFETS

Choosing suitable MOSFETs is extremely important to achieve high power conversion efficiency for the converter. For a buck converter, suitable MOSFETs should not only meet the requirement of voltage and current rating, but also ensure low power loss. VDD can be connected to the 5-V rail when Ciclon FETs are used. But when less expensive FETs are used, direct gate drive facilitates the use of a higher drive voltage (such as V_{IN}) to boost the efficiency.

High-Side MOSFET

Power loss of the high-side MOSFETs primarily consists of the conduction loss (P_{COND1}) and the switching loss (P_{SW1}).

The conduction loss of the high-side MOSFET is the I^2R loss in the MOSFET's on-resistance, $R_{DS(on)1}$. The RMS value of the current passing through the top MOSFET depends on the average load current, ripple current and duty cycle the converter is operating.

$$I_{RMS1} = \sqrt{D \times \left((I_{OUT})^2 + \frac{(I_{RIPPLE})^2}{12}\right)}$$

(9)

The conduction loss can, thus, be calculated as follows.

$$P_{COND1} = (I_{RMS1})^2 \times R_{DS(ON)1}$$

(10)

Product Folder Link(s): *PS 51113*, *PS 1163*

Also, the switching loss can be approximately described as

$$P_{SW1} = V_{IN} \times \left(\left(\frac{I_{D1} \times t_{S1}}{6} \right) + \left(\frac{I_{D2} \times t_{S2}}{2} \right) \right) \times f_{SW}$$

(11)

where

- I_{D1} and I_{D2} are the current magnitudes at the time instance when the MOSFETs switch

$$I_{D1} = I_{OUT} - \frac{1}{2} \times I_{RIPPLE} \quad and \quad I_{D2} = I_{OUT} + \frac{1}{2} \times I_{RIPPLE}$$

(12)

where

- t_{s1} is the MOSFET switching-on time
- t_{s2} is the MOSFET switching-off time

Therefore, the total power loss of the high-side MOSFET is estimated by the sum of the above power losses,

$$P_{HFET\_Loss} = P_{COND1} + P_{SW1}$$

(13)

Synchronous Rectifier MOSFET Power Loss

Power loss associated with the synchronous rectifier (SR) MOSFET mainly consists of $R_{DS(on)}$ conduction loss, body diode conduction loss and reverse recovery loss.

Similarly to the high-side MOSFET, the conduction loss of the SR MOSFET is also the I^2R loss of the MOSFET's on-resistance, $R_{DS(on)2}$. Since the switching on-time of the SR MOSFET is $(1-D) \times T$, where T is the duration of one switching cycle, the RMS current of the SR MOSFET can be calculated as follows.

$$I_{RMS2} = \sqrt{(1-D) \times \left(\left(I_{OUT} \right)^2 + \frac{\left(I_{RIPPLE} \right)^2}{12} \right)}$$

(14)

The symchronous rectifier (SR) MOSFET conduction loss is

$$P_{COND2} = \left(I_{RMS2} \right)^2 \times R_{DS(ON)2}$$

(15)

The body diode conduction loss is

$$P_{COND3} = I_{OUT} \times V_F \times t_D \times f_{SW}$$

(16)

where

- V_F is the forward voltage of the MOSFET body diode
- t_D is the total conduction time of the body diode in one switching cycle

The body diode recovery time – the time it takes for the body diode to restore its blocking capability from forward conduction state, determines the reverse recovery losses.

$$P_{RR} = \frac{1}{2} \times Q_{RR} \times V_{IN} \times f_{SW}$$

(17)

where

- Q_{RR} is the reverse recovery charge of the body diode

Therefore, the total power loss of the SR MOSFET is estimated by the sum of the above power losses.

$$P_{SR\_Loss} = P_{COND2} + P_{COND3} + P_{RR}$$

(18)

Feedback Loop Compensation

Since TPS51113/TPS51163 utilizes voltage-mode control for buck converters, Type III network is recommended for loop compensation. Suitable poles and zeros can be set by choosing proper parameters for the loop compensation network.

To calculate loop compensation parameters, the poles and zeros for the buck converter should be obtained. The double pole, determined by the L, and C_{OUT} of the buck converter, is located at the frequency as shown in the following equation.

$$f_0 = \frac{1}{2\pi \times \sqrt{L \times C_{OUT}}}$$

(19)

Also, the ESR zero of the buck converter can be achieved.

$$f_Z = \frac{1}{2\pi \times ESR \times C_{OUT}}$$

(20)

Figure 8 shows the configuration of Type III compensation. The transfer function of the compensator is described in Equation 21. Also, poles and zeros for the Type III network are shown in Equation 22 through Equation 26.
Figure 8. Type III Compensation Network

$$G(s) = \frac{(sR_2C_1 + 1) \times (s(R_1 + R_3)C_3 + 1)}{sR_1(C_1 + C_2) \times \left(s\left(\frac{R_2C_1C_2}{C_1 + C_2}\right) + 1\right) \times (sR_3C_3 + 1)}$$

(21)

$$f_{Z1} = \frac{1}{2\pi \times R_2 \times C_1}$$

(22)

$$f_{P1} = \frac{1}{2\pi \times R_2 \times \left(\frac{(C_1 \times C_2)}{(C_1 + C_2)}\right)}$$

(23)

$$f_{P2} = \frac{1}{2\pi \times R_3 \times C_3}$$

(24)

$$f_{Z2} = \frac{1}{2\pi \times (R_1 + R_3) \times C_3}$$

(25)

$$f_C = \frac{1}{2\pi \times R_1 \times (C_1 + C_2)}$$

(26)

f_{P1} is usually used to cancel the ESR zero in Equation 20. f_{P2} can be placed at higher frequency in order to attenuate the high frequency noise and the switching ripple. f_{Z1} and f_{Z2} are chosen to be lower than the switching frequency, and f_{Z1} is lower than resonant frequency f_0. Suitable values can be selected to achieve the compromise between high phase margin and fast response. A phase margin of over 60° is usually recommended. Then, the compensator gain is chosen to achieve the desired bandwidth.

The value of R_{BIAS} is calculated to set the output voltage V_{OUT}.

$$R_{BIAS} = \frac{0.8 \times R_1}{V_{OUT} - 0.8}$$

(27)

Layout Considerations

For the grounding and circuit layout, certain points need to be considered.

- It is important that the signal ground and power ground properly use separate copper planes to prevent the noise of power ground from influencing the signal ground. The impedance of each ground is minimized by using its copper plane. Sensitive nodes, such as the FB resistor divider and VOS resistor divider, should be connected to the signal ground plane, which is also connected with the GND pin of the device. The high power noisy circuits, such as synchronous rectifier, MOSFET driver decoupling capacitors, the input capacitors and the output capacitors should be connected to the power ground plane. Finally, the two separate ground planes should be strongly connected together near the device by using a single path/trace.
- A minimum of 0.1-µF ceramic capacitor must be placed as close to VDD pin and GND pin as possible with a trace at least 20 mils wide, from the bypass capacitor to the GND. Usually a capacitance value of 1 µF is recommended for the bypass capacitor.
- The PowerPAD should be electrically connected to GND.
- A parallel pair of trace (with at least 15 mils wide) connects the regulated voltage back to the chip. The trace should be away from the switching components. The bias resistor of the resistor divider should be connected to the FB pin and GND pin as close as possible.
- The component placement of the power stage should ensure minimized loop areas to suppress the radiated emissions. The input current loop is consisted of the input capacitors, the main switching MOSFET, the inductor, the output capacitors and the ground path back to the input capacitors. The SR MOSFET, the inductor, the output capacitors and the ground path back to the source of the SR MOSFET consists of the output current loop. The connection/trace should be as short as possible to reduce the parasitic inductance.
- Connections from the drivers to the respective gate of the high-side or the low-side MOSFET should be as short as possible to reduce stray inductance. A trace of 25 mils or wider is recommended.
- Connect the overcurrent setting resistor from LDRV_OC to GND close to the device.

TPS51113 Design Example

The following example illustrates the design process and component selection for a single output synchronous buck converter using the TPS51113. The schematic of a design example is shown in Figure 9. The specification of the converter is listed in Table 2.

Table 2. Specification of the Single Output Synchronous Buck Converter

|	PARAMETER	TEST CONDITION	MIN	TYP	MAX	UNIT
V_{IN}	Input voltage		10.8	12	13.2	V
V_{OUT}	Output voltage			1.6		V
V_{RIPPLE}	Output ripple	I_{OUT} = 10 A		2% of V_{OUT}		V
I_{OUT}	Output current			10		V
f_{SW}	Switching frequency			300		kHz

Figure 9. Design Example, 12 V to 1.6 V/10 A DC-DC Converter

Choosing the Inductor

Typically the peak-to-peak inductor current ΔI is selected to be approximately between 20% and 40% of the rated output current. In this design, I_{RIPPLE} is targeted at around 30% of the load current. Using Equation 2.

$$L = \frac{(V_{IN} - V_O) \times V_O}{V_{IN} \times I_{RIPPLE} \times f_{SW}} = 1.534\,\mu H$$

(29)

Therefore, an inductor value of 1.5 µH is selected in practical, and the inductor ripple current is 3.08 A.

Calculating Output Capacitance

Minimum capacitance value can be calculated according to the demand of the load transient response. Considering 0-A to 10-A step load and 10% overshoot and undershoot, the output capacitance value can be estimated by using Equation 6,

$$C_{OUT} = \frac{L \times \left((I_{OH})^2 - (I_{OL})^2 \right)}{\left| (V_f)^2 - (V_i)^2 \right|} = 279\,\mu F$$

(30)

A 470-µF POS-CAP with 18-mΩ ESR and a 47-µF ceramic capacitor are paralleled for the output capacitor.

Input Capacitor Selection

Considering 100 mV $V_{RIPPLE(Cin)}$ and 50 mV $V_{RIPPLE(ESR\_Cin)}$, the input capacitance value and ESR value can be calculated according to Equation 7 and Equation 8, respectively.

$$C_{IN(min)} = \frac{I_{OUT} \times V_{OUT}}{V_{RIPPLE(C_{IN})} \times V_{IN} \times f_{SW}} = 44\,\mu F$$

(31)

$$ESR_{C_{IN}} = \frac{V_{RIPPLE(ESR\_C_{IN})}}{\left(\dfrac{(I_{OUT} + I_{RIPPLE})}{2}\right)} = 4.3\,m\Omega$$

(32)

Therefore, two 22-μF ceramic capacitors with 2-mΩ ESR can meet this requirement.

Choosing MOSFETS

High-Side MOSFET Power Loss

BSC079N03S is used for the high-side MOSFET. The on-resistance, $R_{DS(on)1}$ is 7.9 mΩ. MOSFET switching-on time (t_{s1}) and switching-off time (t_{s2}) are approximately 9 ns and 24 ns, respectively. By using Equation 9 through Equation 13, the total power loss of the high-side MOSFET is estimated.

$$P_{HFET\_Loss} = P_{COND1} + P_{SW1} = (I_{RMS1})^2 \times R_{DS(on)1} + V_{IN} \times \left(\frac{I_{D1} \times t_{S1}}{6} + \frac{I_{D2} \times t_{S2}}{2}\right) \times f_{SW} = 649\,mW$$

(33)

Synchronous Rectifier MOSFET Power Loss

BSC032N03S is used for the synchronous rectifier MOSFET. The on-resistance, $R_{DS(on)1}$ is 3.2 mΩ. The body diode has a 0.84-V diode forward voltage and 15-nC reverse recovery charge. The output driver deadtime is 30 ns. By using Equation 14 through Equation 18, the total power loss of the synchronous MOSFET is estimated,

$$P_{SR\_Loss} = P_{COND2} + P_{COND3} + P_{RR} = \left[I_{RMS2}\right]^2 \times R_{DS(on)2} + I_O \times V_F \times t_D \times f_{SW} + \frac{1}{2} \times Q_{RR} \times V_{IN} \times f_{SW} = 382\,mW$$

(34)

Feedback Loop Compensation

Since TPS51113 and TPS51163 utilize voltage-mode control for buck converters, Type III network is recommended for loop compensation. The converter utilizes a 1.5-μH inductor and 470-μF capacitor with 18-mΩ ESR. The double pole, determined by the L, and C_{OUT} of the buck converter, is derived by Equation 19

$$f_0 = \frac{1}{2\pi \times \sqrt{L \times C_{OUT}}} = 6.0\,kHz$$

(35)

Also, the ESR zero of the buck converter can be achieved by using Equation 20.

$$f_Z = \frac{1}{2\pi \times ESR \times C_{OUT}} = 18.8\,kHz$$

(36)

Product Folder Link(s): TPS51113, TPS51163

Figure 10 shows the detailed parameters used for the Type III compensation. Also, poles and zeros for the Type III network are derived based on Equation 22 through Equation 26.

Figure 10. Parameters for Type III Compensation Network

$$G(s) = \frac{(sR_2C_1+1) \times (s(R_1+R_3)C_3+1)}{sR_1(C_1+C_2) \times \left(s\left(\frac{R_2C_1C_2}{C_1+C_2} \right) + 1 \right) \times (sR_3C_3+1)}$$

(37)

$$f_{Z1} = \frac{1}{2\pi \times R_2 \times C_1} = 2.7\,\text{kHz}$$

(38)

$$f_{Z2} = \frac{1}{2\pi \times (R_1+R_3) \times C_3} = 9.2\,\text{kHz}$$

(39)

$$f_{P1} = \frac{1}{2\pi \times R_2 \times \left(\frac{(C_1 \times C_2)}{(C_1+C_2)} \right)} = 17.8\,\text{kHz}$$

(40)

$$f_{P2} = \frac{1}{2\pi \times R_3 \times C_3} = 149.4\,\text{kHz}$$

(41)

$$f_C = \frac{1}{2\pi \times R_1 \times (C_1+C_2)} = 3.1\,\text{kHz}$$

(42)

f_{P1} is used to cancel the ESR zero. f_{P2} is placed at higher frequency to attenuate the high-frequency noise and the switching ripple. f_{Z1} is lower than resonant frequency f_0.

The value of R_{BIAS} is calculated to set the output voltage V $_{OUT}$ by using Equation 27.

$$R_{BIAS} = \frac{0.8 \times R_1}{V_O - 0.8} = 2\,\text{k}\Omega$$

(43)

Based on Equation 43 and the power stage parameters, the bode-plot by simulation is shown in Figure 10 (V_{IN}=12 V and I_{OUT}=0 A). The achieved cross-over frequency is approximately 35.7 kHz, and the phase margin is approximately 60°.

**Figure 11. Bode Plot of the Design Example Circuit by Simulation (V$_{IN}$=12 V and I$_{OUT}$=0 A)**

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No−Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

        C. Publication IPC−7351 is recommended for alternate designs.
        D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat−Pack
            Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets
            for specific thermal information, via requirements, and recommended board layout. These documents are available at
            www.ti.com <http://www.ti.com>.
        E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should
            contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
        F. Customers should contact their board fabrication site for minimum solder mask web tolerances between signal pads.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
