

JFET-Input Operational Amplifiers

Low Supply Current (LF155)

High-Speed (LF156)

FEATURES

- *Guaranteed* Offset Voltage Drift on All Grades
- *Guaranteed* Slew Rate on All Grades
- *Guaranteed* Low Input Offset Current 10pA Max.
- *Guaranteed* Low Input Bias Current 50pA Max.
- *Guaranteed* High Slew Rate (156A/356A) 10V/ μ s Min.
- Fast Settling to 0.01% 1.5 μ s

APPLICATIONS

- Output Amplifiers for D/A Converters
- Fast Sample and Hold Circuits
- High Speed Integrators
- Photocell Amplifiers
- High Input Impedance Buffers

DESCRIPTION

Linear Technology's LF155/156 series features several improvements compared to similar types from other manufacturers: offset voltage drift with temperature and slew rate are guaranteed on all grades, not just on the more expensive "A" grades. Other specifications such as voltage gain and high temperature bias and offset currents are also improved.

The industry standard LF155/156 devices exhibit phase reversal at the output when the negative common-mode limit at the input is exceeded (i.e., from $-12V$ to $-15V$ with $\pm 15V$ supplies). This can cause lock-up in servo systems. As shown below, Linear Technology's LF155/156 does not have this problem due to unique phase reversal protection circuitry. For applications requiring higher performance, see the LT1055 and LT1056 data sheets.

2

The ● denotes the specifications which apply over the full operating temperature range. The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Unless otherwise specified, the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Unless otherwise stated, these test conditions apply:

	LF155A/156A LF155/156	LF355A/356A	LF355/356
Supply Voltage, V _S	±15V ≤ V _S ≤ ±20V	±15V ≤ V _S ≤ ±18V	V _S = ±15V
T _A	-55°C ≤ T _A ≤ +125°C	0°C ≤ T _A ≤ +70°C	0°C ≤ T _A ≤ +70°C

and V_{OS}, I_B and I_{OS} are measured at V_{CM} = 0.

Note 3: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D. T_J = T_A + Θ_{JA} P_D where Θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 4: The temperature coefficient of the adjusted input offset voltage changes only a small amount (0.5μV/°C typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.

Note 5: Settling time is defined here for a unity gain inverter connection using 2kΩ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter.
